

THE GETTY CENTER LIBRARY

1870  
The first of the year was a  
very dry one, and the crops  
were much injured. The  
winter was also very dry,  
and the ground was very  
hard. The spring was also  
very dry, and the crops  
were much injured. The  
summer was also very dry,  
and the crops were much  
injured. The autumn was  
also very dry, and the  
crops were much injured.  
The winter was also very  
dry, and the ground was

# THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 2435. VOL. LIV.

FRIDAY, JANUARY 4, 1907.

PRICE TWOPENCE.

## Contents.

## EX CATHEDRA.

**"Colour Photography."** We have pleasure in announcing that, commencing with the present issue, we shall issue a monthly supplement to the **BRITISH JOURNAL** devoted exclusively to colour photography. This step has not been taken without careful consideration on our part. The growing importance of the subject will inevitably call before very long for a larger allocation of space than we can grant in the pages of the **JOURNAL**, and even in the present state of colour photography literature it is very desirable to have a publication to which reference can be made. In the first "supplement," which will be appended as a regular feature to the first issue of the **JOURNAL** for each month, several branches of colour photography are represented, and we commence also to pull up arrears by initiating a synopsis of the British patents dealing with photographic reproduction in colours. In other respects it is our intention to devote the Supplement to the aspects of colour photography for which the pages of the **JOURNAL** are not at all times at disposal.

\* \* \*

**The Assistants.** The letter from Mr. V. Doust on another page does credit to the energy and disinterestedness of that gentleman, while it also shows him to be endowed with a degree of optimism which is, perhaps, not shared by others who have worked on behalf of the employed classes in photography. The response to Mr. Doust's letters in the **JOURNAL** and to whatever private communications he has addressed has been ninety-three "members" of the unborn society and seventy-two enquiries. Considering that membership at present means nothing at all, we may put "members" and enquirers together at a total of a round one hundred and seventy—by no means a large representation of the thousands of assistants in the country; but nevertheless a distinct expression, which possibly will merit consideration by the Professional Photographers' Association. Since we hold very strongly that in any business the interests of employers and employed are identical, and that both increase in the same ratio, we hope that it may be feasible to draft a scheme under which assistants may become more nearly related to the Professional Photographers' Association. We would advise all our friends not to be over-sanguine, for such propagandist work in the past has proved of the most discouraging description. Certain of the suggestions of Mr. Doust's correspondents—we will not particularise—may be dismissed at once. Yet we believe we discern beneath these inept propositions the signs of a desire towards raising the photographic profession as a whole. We hope the desire may be sufficiently widespread.

## SUMMARY.

We much regret to announce the deaths of:—  
Mr. Thomas R. Dallmeyer. (P. 10.)  
Mr. J. T. Sandell. (P. 11.)  
Mr. George Bishop. (P. 11.)

Instructions for working the chromium intensifier are given by Mr. Welborne Piper, who, with Mr. D. J. Carnegie, originated the process. (P. 3.)

M. Demachy, in a criticism of English pictorial photography, thinks it is too "photographic." "Photographic characteristics," says M. Demachy, "are anti-artistic." (P. 2.)

Dr. John Bartlett has published in the "Camera" a uranium sensitiser sufficiently rapid for gaslight printing. (P. 7.)

Herr E. Valenta has given the formula for an extra-rapid emulsion for P.O.P. (P. 4.)

A fine example of photography applied to advertisement literature has been supplied by the proprietors of "McClure's Magazine." (P. 45.)

A distinctly humorous patent (P. 12) is the only patent news of the week.

The Royal Photographic Society announces an exhibition by members of the societies affiliated to it. (P. 15.)

## "COLOUR PHOTOGRAPHY" SUPPLEMENT.

M. Ducos du Hauron, the veteran inventor of colour processes, announces a new departure in direct colour photography. (P. 1.)

Points of importance in preparing colour filters are the subject of an article by Mr. E. J. Wall. (P. 4.)

Mr. E. Grills contributes a series of hints on the practical working of pinatype. (P. 2.)

A chronology of colour patents commences on Page 6.

An emulsion for the Lippmann process. (P. 3.)

### The Temperature of Developing Solutions.

During the present spell of cold weather trouble is likely to arise with the developing and other solutions employed in dark-rooms and the other work-rooms about the photographic business. A day or two ago we were in the developing-room of a photographer, who was handling some large batches of plates, employing a two-solution metol-hydroquinone developer. No sooner was the developer applied to the plates than they were seen to be covered with a whitish-grey sludge. Development continued slowly, but about fifteen minutes was required to gain sufficient density. Not only did the cold solution allow some of the constituents of the developer to crystallise out, but the hydroquinone was practically inert. For the second batch of plates the dish was thoroughly warmed with hot water. The measure was also warmed, and instead of taking equal parts of the metol and hydroquinone solutions, equal parts of metol, hydroquinone and warm water were taken, the developer thus being actually weaker. Ample density was now obtained, however, in about seven minutes. By far the safest way of dealing with the cold-weather difficulties is to raise the temperature of the dark-room itself, for then not only the plates and developer, but the photographer also, benefits by the more normal degree of warmth. Good results cannot be obtained if the fingers, and more particularly the feet, are cold.

\* \* \*

### The Question of Returned Proofs.

We published last week an extract from an American contemporary on the ever-recurring question of proofs. It is, we believe, the custom in many British studios to send out untuned P.O.P. prints from the retouched negatives, and this method seems a fairly satisfactory one, being both inexpensive and expeditious, while the result is not displeasing. We have, however, quite recently met with cases where such untuned prints have been sent to some other photographer or photographic chemist to be "made permanent," and quite evidently the proofs in question have not been charged for by the photographer. We know that in many cases the rule that "all proofs must be paid for" is a bone of contention, and as the less chances of friction exist the more smoothly will the business side of the establishment run, it seems advantageous to take steps to ensure untuned prints being of no use to the client who retains them. It has been suggested—jocularly, no doubt—that such proofs might be stamped with a rubber stamp, "not paid for." We think the best course, however, is to use a perforating stamp similar to that used for perforating the amount of a cheque across it, and the lettering might read, "unfinished proof." If this were punched, not across the face, but quite near to it, it would effectually prevent the proof being used even if it were toned. Why should not one of the trade houses supply such a perforating stamp?

\* \* \*

### Postcard Possibilities in Landscapes.

Despite the well-filled shop windows, in the domain of topographical postcards, there would seem to be still very large scope for professional photographers. We have always encouraged this work amongst photographers, and we shall continue to do so, only adding that they should have more regard to pictorial attractiveness of subject and better technical nicety in production. Without these desiderata it is hopeless to attempt to cope with the seductive lithographs and three-colour work of the large publishing firms. Our own bitter experience is that in the search for mementos of holiday trips or the records of a journey, to send home to some fair young collector, we have been faced with the most atrocious examples of pictorial landscape art it has ever been our misfortune

to meet. Any tyro in a club who could produce work as bad would be shamed into despair by his fellows. "The new church" at close quarters, or an interminable street of houses with nothing but topography to recommend them, do not make saleable cards, except to the poor purchaser who has to take them against his will for want of anything better. Artists are so plentiful nowadays that we should have thought any local photographer could easily obtain advice as to selection of subject, if that were a doubtful matter in his mind. One constant blemish is the row of grinning children in soiled garments, once their Sunday best, bought from the cheap clothier's. There is no picturesque costume left now in the country. Where is the necessity for suffering this crowd of little guys to spoil a view? Really good pictures, well printed, of quaint villages and towns, to say nothing of open country scenes of popular interest, such as Hindhead and the "Devil's Dyke," for example, would find a sale far beyond the locality of their situation.

\* \* \*

### Sepia Platinotypes.

The damp winter days being trying for platinotype paper, sepia especially, and causing parts of a print (the damper) to develop much darker than the remainder, it is important to consider a remedy for this trouble. This kind of "staining" may become very troublesome in printing Cosways, or prints having a white masked border. With these the paper is usually much larger than the negative, and, as a result, the border is not pressed tightly between the rubber backing and the negative. With prolonged exposure the damp attacks this unprotected border, causing a faint darkening on development. The only remedy is to dry the pad, rubber, and backing thoroughly before printing, and to make the exposure to light as short as possible. Another kind of marking, when printing Cosways from masked negatives, is caused by the light creeping through the negative. With this work the mask is usually placed on the back of the negative, to soften the outline, the result being that the light penetrates some distance in a horizontal direction. Should the edge of the mask be near the edge of the negative, the paper will be tinted beyond the edge of the latter. To avoid this, the negative should be given a safe edge of black paper, not as in the carbon process, but bound as with lantern slides. This will effectually stop the edge of the glass from acting the part of a prism in concentrating the faint light it receives.

### M. DEMACHY ON PERSONAL EXPRESSION VERSUS PHOTOGRAPHY.

It is truly mortifying to have the object of our admiration turn round and hit out. Only on that account are we vexed that M. Demachy, whom all in this country have looked up to as the pink of a kindly artist, should occupy four pages of "La Revue de Photographie" in derision of the "new school in England." He takes as his text a few passages from journals which reviewed the recent salon (not the BRITISH JOURNAL OF PHOTOGRAPHY, let us hasten to explain), and with his eye upon the general tenor of complaint that ran through the Press about that show, he reads us a homily, healthy, although severe. English standards he finds all too strongly directed in favour of "pure photography," and critics generally too ready to make a work stand or fall by its allegiance to methods of non-control. This tendency constitutes what is called the "new school," though, as everybody knows, it is old enough. M. Demachy represents us saying, "avec une certaine pompe," that "henceforth a print after nature cannot be beautiful except on the condition that it offer photographic characteristics and the qualities of the

medium." He instances three pictures by Hollyer, Craig Annan, and Cadby in the last salon. Some unfortunate critic, it appears, likened Mr. Hollyer's portrait to an oil painting, adding that it was of little merit to prove that photography could do as well as other processes (which, we submit, it certainly did not in this case), but that progress consisted, on the other hand, in showing the power of photography in directions unapproachable by other means. Remarks of a similar nature are quoted in reference to Mr. Craig Annan's "Hampton Court," and, finally, Mr. Cadby is championed. The blame hurled at the author of snow sketches—that he had aped a dry-point etching—is taken up by M. Demachy and handed to him again as praise. By some short cut in logic, wherein we confess to losing ourselves, our courtly neighbour arrives at this: "That if dry-point did not exist, Mr. Cadby would be the father of a little masterpiece." The truth is, perhaps, that if dry-point did not exist, Mr. Cadby would be emulating something else—merely that.

"Do not the writers of the English school understand that the graphic art is all a matter of sensation, and ought to be judged by the eyes? . . . Would they want a certificate of origin in order to know that an image, in black and white is qualified to be a work of art? Photographic characteristics are, and always have been," says M. Demachy, "anti-artistic characteristics."

All this, at any rate, should give us pause. No doubt there are many who draw near to "controlled" prints in a frame of mind hopelessly biassed. We want the widest possible outlook if all the cant about art is to be anything more than mere snobbery. The position of M. Demachy is quite unassailable, and nobody could rightly say that personal expression for which he fights is not the chiefest

thing of all in the making of a work of art. But M. Demachy's width of vision in front has closed his eyes altogether to beauties behind. His point of view is fine enough, but there is another—namely, that of the man who sees in camera pictures certain desirable peculiarities he wishes to develop. With M. Demachy, photography, as he has admitted, "steps out." His triumphs are not due to it at all. He uses it as a hack, a menial, a mere scaffolding, to be ultimately eliminated. It shares no honours of his; and who shall say him nay? Our only point is that, to be consistent, he should let his works step out of photographic exhibitions, out of the photographic Press (we hope he will do nothing of the kind), and out of a photographic court of adjudication. They are for the art journals. They are, indeed, like paintings, to be treated as unique specimens.

It is difficult to see that he can have any quarrel with those who, taking up his own cue, deny to these things the name of photography. And it is as hard to understand that he should think the aims and ideals of certain clever workers, who, like Mr. Fredk. Evans, for example, are content to strive for artistic results without letting photography give them the slip, by "stepping out." M. Demachy is hard on the critics, but whenever anything comes along that is really fine by any methods, we believe the critics point it out with admiring voices; yet they should not be expected to act like indulgent mothers to inventive brats. Rather ought they to object to the posing of cliques who, in the name of art, bolster up each other's tentative and experimental groupings displayed in exhibition galleries ostensibly devoted to photographs, at the same time that they deny all artistic claims to photography *per se*.

## CHROMIUM INTENSIFICATION.

I SEE that several correspondents have asked for further information on the subject of intensification by redevelopment after bleaching with potassium bichromate and hydrochloric acid. It is asked if the process is meeting with favour. This must surely be the case, since the intensifier has long been upon the market in liquid form, and has quite recently appeared in an improved, solid, "scaloid" form. My own experience is that the intensifier is all that can be desired, if only very reasonable care is exercised. From the time when first suggested by Dr. Eder, right up to a couple of years ago, it was considered to be a process dependent on redevelopment only. The investigation carried out by Mr. D. J. Carnegie and myself proved, however, that it was really an additive process similar to many others. The mechanism is fairly simple to understand. The addition of hydrochloric acid to potassium bichromate produces potassium chlorochromate, which is a powerful oxidiser. This chlorochromate oxidises the silver into one of the mysterious photochlorides of silver, which is readily developable without any exposure to light, and at the same time the silver decomposes the chlorochromate, reducing from it a chromium oxide compound that reinforces the image and adds to its density. The standard bleaching solution employed contains ten grains of potassium bichromate and five minims of hydrochloric acid in every ounce, and experience shows that amidol is the most satisfactory developer to use. With the fluid ready-prepared intensifier metol-hydroquinone is commonly supplied, but with the solid form amidol is included.

### Sources of Failure.

The commonest source of trouble is over-exposure to light. Exposing the bleached image to strong light brings on a

condition akin to solarisation, and renders it almost undevelopable. Exposure to strong light during development also at times produces bad development stains. Many workers seem to have failed to recognise the fact that so-called non-staining developers, though non-staining in the dark, will produce most violent and immovable stains if used in strong sunlight. Other troubles are due to attempts to bleach the image with an exhausted solution, and to insufficient washing between bleaching and development. The effect is fairly constant if the negative is not allowed to remain too long in the bleaching bath, and if the proportions of the latter are strictly adhered to. Too long an immersion, or an excess of acid, gives less intensification. Compared with other intensifiers, the results are far more reliable and more constant than those obtained with mercury and ammonia or mercury and soda sulphite, while the density given is intermediate between the best densities attainable with these two intensifiers. Scientifically the results are not so exact as with mercury and ferrous oxalate, but the average printing density attained is about the same, while most people find the process much easier to apply. Many fail completely with the mercury process, though it is not clear why they do so.

### Three Simple Operations.

In applying the chromium process, the plate should be immersed in the bleaching solution until all greyness has disappeared from the back of the image. The plate is next washed in running water until all yellow stain has disappeared and a brownish-buff image is left. The image is then developed in an amidol developer without bromide; a strong developer containing about five grains amidol to the ounce being advisable. Bleaching takes about two minutes; washing about

twenty (in a grooved syphon washing tank), and development about five minutes. The whole process should be conducted in diffused daylight or by gaslight. Sunlight should be avoided, and too much diffused light when washing is undesirable. Development should be carried out as soon as washing is complete. Drying between washing and development should not be attempted.

#### The Results of Intensification.

Photometric tests show that the process tends to increase contrast, as the increase of density is greater in the high tones than in the low ones. As a natural consequence, a very thin negative sometimes requires more than one application of the process, but three applications is the most that is likely to be required. Ordinarily one is sufficient. The increase is very fairly regular from the low tones up to the high ones, excepting when the high tones show halation. The following figures represent the ratios of the densities of intensified H. and D. slips to the densities of the unintensified originals:—

C.M.S.	.166	.312	.625	1.25	2.5	5	10	20
Slip 1 .....	1.16	1.33	1.42	1.4	1.48	1.66	1.54	1.5
Slip 2 .....	1.14	1.26	1.35	1.41	1.54	1.55	1.48	1.46
Slip 3 .....	1.16	1.38	1.46	1.4	1.4	1.33	1.36	1.34
Slip 4 (= Slip 1 re-intensified) .....	1.03	1.17	1.2	1.17	1.09	1.14	1.17	1.19

The 5, 10, and 20 c.m.s. densities are all halated, and it will be noticed that the ratio of increase of density falls off in the last two tones, for some not very clear reason. It would be of interest to know if similar effects have been observed with other intensifiers when halation is present. Slips 1 and 2 show a very regular increase of contrast up to the 5 c.m.s. density. Slip 3 is not so regular, but an abnormal bleaching

solution, calculated to give less density was used in this slip, and the effect is more noticeable in the high-lights than elsewhere. The low tones are practically affected to the same degree as in slip 1, which is from the same plate. Slip 4 shows the result of a second intensification of slip 1. Here the tendency to increase contrast has disappeared. The readings are irregular, but suggestive of a more or less uniform effect in all tones. The ratio is much lower than the average ratio of the first intensification, and this is always the case. Only one test of the effect of repetition has yet been made, and further tests are necessary. In fact, all these tests must be repeated. Slips 1 and 2 are from separate plates that received the same exposure, but different times of development with metol-hydroquinone. The intensifying solutions were the same, and the results are fairly uniform. The denser plate (slip 1) shows higher ratios, with one exception.

Practical experience shows that this chromium process is admirably suited to the production of line negatives. A properly exposed negative on a process plate is developed with hydroquinone, and after fixing it is cleared with Farmer's reducer. The chromium intensifier then turns it into a perfect "black and white" negative. The exposure must be a nearly "correct" one in the first instance.

The bleaching solution can be applied to a plate that has only been rinsed after fixing, for the result is a perfect hypo eliminator, and produces no sulphur bloom. This procedure is sometimes useful, but it is generally necessary to apply a second fresh bleaching bath, as the first one is quickly exhausted by the hypo. I do not recommend this method of work, and prefer to wash for ten or twenty minutes before bleaching. The fact that perfect washing is unnecessary is, however, a great advantage, shared apparently by only one other intensification process, that is, the one known as the iodine process.

C. WILBORNE PIPER.

## RAPID BROMIDE P.O.P. EMULSION.

PROF. E. VALENTA, who read a paper before the Congress of Applied Chemistry, in Rome (B.J., 1906, p. 466), in which he suggested the use of silver bromide with excess of nitrate of silver emulsified in collodion for printing-out, has since then been continuing his experiments, particularly as regards the best proportions of silver to bromide the quantity of citric acid, etc. In the current number of "Das Atelier des Photographen," he gives the following method of making such an emulsion.

The best proportion between the bromide and silver is 1 of the former to 5 or 6 of the latter. Whilst with chloro-citrate emulsions, the addition of part of the silver salts in the form of ammonio-nitrate is especially satisfactory, particularly when the paper is to be used for gold and platinum toning, it is of no use for a bromo-citrate emulsion. Further, the proportion of citric acid does not exert the same action as in a chloro-citrate emulsion. The best results were obtained with a small proportion of citric acid.

As regards the influence of the metal, with which the bromine is combined, on the character of the emulsion, this is somewhat important. Calcium, strontium, and lithium bromides gave the most satisfactory results. With other bromides which are also soluble in alcohol, such as those of magnesium and cadmium, flat results were obtained, whilst other bromides, for instance, mercury bromide gave very insensitive and useless emulsions.

Emulsions made with calcium bromide printed more or less of an intense red colour, whilst strontium bromide emulsions gave dirty-violet prints. Both assume fairly quickly, in the

ordinary gold and combined fixing baths, purple brown to violet black tones.

#### An Emulsion for Triple-Speed P.O.P.

The following formula will give a bromo-citrate emulsion with very satisfactory results:—

A.—Collodion (2½-3 per cent.).....	500 ccs.
B.—Citric acid .....	10 gms.
Alcohol .....	40 ccs.

Dissolve and add

Strontium bromide (40 per cent. sol.).....	4 ccs.
Glycerine-alcohol (1:1) .....	4 ccs.

C.—Silver nitrate .....	10 gms.
-------------------------	---------

Dissolve in as little hot water as possible and add

Alcohol .....	40 ccs.
D.—Ether .....	80 ccs.

A and B should be mixed by daylight, and then C added gradually with constant shaking, by yellow light, and then finally D. The yellow creamy emulsion should then be allowed to stand for some minutes, filtered through cotton wool and coated.

The emulsion gives a good printing paper that will keep, and the sensitiveness is about three times as great as that of commercial collodio-chloride paper. The prints on this paper can be easily toned in the usual separate and combined baths. The prints lose but a little during toning and fixing, about 3 to 4 deg. on Vogel's scale photometer, show no tendency to bronzing, and possess a gradation greater than that of albumenized paper, so that this paper requires plucky negatives full of contrast.

**Extra-rapid P.O.P. for Flat Negatives.**

An emulsion which gives brilliant printing paper suitable for softer negatives can be obtained by replacing some of the strontium bromide in the above formula by a corresponding quantity of uranium bromide. Papers prepared with this emulsion have the same gradation as albumenised paper, and suitable negatives give brilliant prints, full of gradation. The sensitiveness of this paper is the same as that of good collodio-chloride paper.

The addition of alcoholic chromates to the bromo-citrate emulsion produce, just as in the case of chloro-citrate emulsions, a great curtailment of the scale of gradation, but the sensitiveness of such papers is considerably greater than that of a paper containing the same proportion of chromic acid. It is easy to obtain in this way a paper for flat negatives, which will give brilliant prints, and yet have a greater sensitiveness than the chromo chloro-citrate paper. Such an emulsion can be prepared by the addition of a solution of 0.8 gms. of calcium bichromate to the above bromo-citrate emulsion. The paper prepared with this emulsion is about half as sensitive as collodio-chloride paper and prints very hard. The scale of the bromo-citrate paper without chromic salts was 20 on the photometer; after addition of the calcium bichromate only eight to nine steps were obtained. The prints lose less than a collodio-chloride paper with chromate, so that so much over-printing is not necessary.

Papers prepared with bromo-citrate emulsions plus chromate

give beautiful platinum tones, and are specially suitable for matt papers for platinum, or combined gold and platinum toning. In this case, however, the prints must be very much over-printed, as they lose considerably when treated to the salt bath, and subsequent platinum toning.

**Chloro Bromide Extra-rapid P.O.P.**

Very satisfactory results were obtained with bromo-citrate emulsions containing a certain percentage of chloride. An emulsion prepared as above, to which was added 0.4 to 0.5 gms. of calcium chloride, printed brilliantly and vigorously, gave pure whites and well-covered shadows; there was very little tendency to bronzing, and the gradation was about the same as that of the chromo-chloro-citrate paper. Such an emulsion can print three times quicker than a good collodio-chloride paper. They tone well in the separate and combined baths, and do not lose much. Shortening of the scale of gradation, and therefore harder printing without reduction of the sensitiveness, is obtained by using an equivalent quantity of uranium chloride for the calcium chloride in the above emulsion. The emulsion thus prepared has greater sensitiveness and greater brilliancy than ordinary collodio-chloride paper. Naturally such emulsions may also be prepared with the addition of calcium bichromate, and are then suitable for even the flattest negatives, but the sensitiveness is lower than that of bromo-citrate plus chromate emulsions, and therefore the latter are preferable.

E. VALENTA.

## PHOTOGRAPHS FOR ADVERTISING PURPOSES.

THE S. S. McClure Co., proprietors of "McClure's Magazine," have issued a book to draw attention to the magazine as an advertising medium. "McClure's Magazine," we should explain, is a monthly of popular literature, to which there is no exact match in this country. It occupies the leading position among its fellows in the United States, the country of its origin. The interest of its newly-issued booklet to ourselves and our readers lies in the illustrations, by means of which McClure's have put into pictorial form a business phrase they

Magazine." The illustrations sufficiently explain themselves—they would be useless if they did not—with the exception, perhaps, of the last two, which occur on a page of a booklet where the manager dwells on the practice of the "Magazine" of exercising a strict censorship over the advertisements which appear in it, in other words, certain shops, those selling patent medicines and hair restorers, are not to be found in the McClure

use to describe their magazine—"The market-place of the World." The variety of ways in which this idea is carried out, chiefly by photographic means, induces us to reproduce half a dozen of the illustrations, which we do with the desire of setting before our readers some examples of the skilful use of photography in forcible advertising. A periodical publication of whatever character lends itself less to pictorial advertisement than the majority of articles which are offered to the public, but in the present instance the designer has had his task lightened by the presentation to him of the idea of a market place. The approbation which he has deserved is extended on account of the technically clever association of this idea with "McClure's

market place. This practice of educating the marketer is a strong point in the McClure appeal to advertisers, and is thus pictorially enforced.

Those photographers who have done little or much in preparing prints for advertisement purposes will admit the excellence of these photographs. Such work, one of the most profitable branches of photography at the present time, is one in which exact instruction is almost impossible. It is a business for men with ideas, and in the absence of the inventive faculty, no amount of study will produce the advertisement photographer.

Yet we draw attention to it here in the belief that some of our readers will find it a source of profit either as a special business, or as an adjunct to their professional portraiture. They have only to look through the illustrated journals of the present day to see how greatly the employment of pictorial and photographic advertisements has grown of late. So great has been the departure of large advertisers in this direction that a special photographic department has been set aside by firms or their advertisement agents to the production of striking and fitting originals. Obviously that is not the best method of obtaining variety in the output, and firms having such arrangements will accept suitable photographs and designs from outsiders as readily as those who are not so provided.

It would be easy to write at length on the essentials to success

in advertisement photography, yet the writer is instantly debarred by the thought that the man who does not know these things instinctively can never be taught them. Advertisement photography is akin to the "popular journalism" which has created it. Both are a produce of the same modern habit of crowding too much into the day. The busy man who must now have news served up in quickly-digestible paragraphs, requires also to be considered in the same way by the merchant who desires to convey information of his wares. Advertisement photography is, in short, the journalist's gift of being "readable" in photographs. The ordinary and commonplace are no good for advertisement photography. There must be selection of subject and originality of treatment—creation of an idea. Hitherto, advertisement photographs have run on the lines of charming girls or well-groomed men holding up somebody's soap, or chocolates, or boots, and represented with a fixed huge smile of satisfaction. The comparatively few variations of this primitive and unconvincing idea to be seen suggest that the number of photographers, with any humour or imagination engaged in such work, must be very small. They should take a

hint from the artists. Harry Furniss' immortal drawing, "I used your soap two years ago," used by Pears' soap, might have been made with almost as good effect by photography.

We are often told that so long as an advertisement draws the reader's attention, it does not matter what it is, the means justify the end, but we do not believe this to be the principle

of the most successful advertisers, for the sufficient reason that the effect made on the reader's mind is of the greatest importance. The reader should be left with the impression that the advertisers are clever not as advertisers only, but in their

business proper. How many advertisements simply call forth the comment, "Smart ad., that," without fixing the reputation of the firm or the quality of the article in the reader's mind. Hence we say that there should be a quality of fitness in

addition to that of attractiveness; the advertisements, pictorial or literary, which embodies both is of the greater sale making value to the advertiser. Established firms with world-wide reputations can afford to dispense with these descriptive qualities in an advertisement, but the innumerable lesser known firms, who constitute the market of the advertisement photographer, need them, and require to have their special wants considered.

## A HIGHLY SENSITIVE GASLIGHT URANIUM PRINTING PROCESS.

THE following contribution to our Philadelphia contemporary, the "Camera," is interesting in reviving once again the employment of uranium salts as the sensitive base of a printing process. We can quite believe the claims made by Dr. Bartlett for the rapidity of printing inasmuch as the same phenomenon is observed when uranium is used with ferric ammonium citrate as the sensitive preparation of a "blue" paper, the invisible or scarcely visible image being developed with solution of potassium ferricyanide. In some experiments which we made some years ago, we were surprised at the rapidity attainable by a formula of this kind. The "potash ammonia" in the sizing formula of Dr. Bartlett is presumably potash alum.—Eds., B.J.

The use of the salts of uranium as a medium for photographic printing is by no means a novelty, nitrate of uranium having been employed as far back as 1854 by Niepce St. Victor with satisfactory results. Some years later, Mr. Burnett, of Edinburgh, Scotland, published results which stimulated inquiry, and in 1870 Mr. Wortly made a sort of collodion emulsion with nitrate of silver and uranium which yielded pleasing tones, but his method did not attain practical application on account of the difficulty attending the manipulation or on account of some secrecy in the process which the inventor did not care to reveal, the process being a patented one.

Some recent experiments in the line of previous investigations which the author has made gave such satisfaction and reduced the time of exposure to such a degree that he believes his method will be of interest to photographers who desire an uranium printing process which may be manipulated like ordinary gaslight papers.

To get the best results with uranium, it is necessary to keep the image on the surface of the paper. A suitable sizing is therefore a necessity. After numerous trials the following method of preparing the paper gave the best results and prevented the image from sinking into the paper.

Take	
(A) Soft gelatine .....	120 grs.
Water .....	32 ozs.

Soak the gelatine for a little while in the water, then heat up to about 120 degrees Fahrenheit.

(B) Potash ammonia .....	60 grs.
Oxalic acid .....	8 grs.
Water .....	10 ozs.

Mix A and B and add four ounces of pure alcohol.

Immerse the sheets of paper in this solution for three minutes and hang up to dry by one corner. When dry re-immerses and hang up to dry in the opposite direction to the first hanging. By this means a very uniform coating may be secured and a brilliant printing image obtained.

Uranium prints are usually made by the printing-out process and the image brought to intensity by a bath of potassium ferricyanide, but usually this plan does not give straight and good tones, and the print is only presentable after toning. The colour is an unpleasant bistre. We prefer the method of development both on account of the rich colour obtained and also on account of the great rapidity by which the impression from the negative is secured.

Uranium combined with silver is not a novelty in printing processes, and the writer does not claim originality in its application. All that is claimed is an adjustment of the proportions and method of development by which an exceedingly sensitive medium is secured which gives pleasing artistic tones and in which an ordinary Welsbach light may be employed for exposures. Make the following solutions:—

Distilled water .....	8 ozs.
Nitrate of silver.....	275 grs.
Nitrate of uranium.....	4½ ozs.

FALLOWFIELD's "Courier," for January, 1907, reaches our table, with particulars of new mounts and announcements of the firm's revision of prices.

A copy of the "Scientist's Pocket Book and Diary" for 1907 has been sent to us by Messrs. James Woolley and Co., Victoria Bridge, Manchester, by whom it is issued for 6d., or in a binding of "Rexine" (artificial leather) for 1s. The diary contains a variety of tabular matter relating to chemical and physical sciences, tables of logarithms, tests for chemical reagents, and a brief formulary of photography. An unexpected item of its contents consists in some pages devoted to the first aid to the injured.

Float the paper on this bath for three minutes and hang it up to dry in a dark chamber. The sensitizing must be done in a dark room.

The paper so prepared keeps (\*) indefinitely, or a long time at least, as platinum paper if kept from light and moisture; but it is absolutely necessary that the paper should be prepared in very subdued light and dried in absolute darkness from the peculiarity which uranium salts possess of absorbing radiations. In fact, should you place the prepared paper upon a white sheet which has been exposed to light and then remove both to a dark place the absorbed light in the white sheet will be sufficient to affect the uranium paper. If an engraving on the white paper be exposed to strong sunshine for some minutes and then be placed in contact with one of the prepared uranium sheets in a book and be kept overnight, an image or negative of the engraving will be produced of considerable intensity. But to return to our process. After exposure, which varies from a flash in bright sunlight to five seconds, according to the density of the negative, a strong image may be evolved by development; thirty seconds in diffused light also yields normally good results; from ten to thirty seconds or a minute at six or eight inches from a Welsbach light is sufficient. Dense negatives, of course, necessitate longer exposures. The paper is also sufficiently sensitive to be used for enlargements with electric light. A longer exposure, however, is demanded—perhaps longer than with bromide paper. But as the results are more like platinum printing and the surface perfectly free from gloss, the method recommends itself to artistic workers. To develop the prints make the developer as follows:—

Water .....	10 ozs.
Proto-sulphate iron .....	1 oz.
Tartaric acid .....	½ oz.
Sulphuric acid .....	1 dr.
Glycerine .....	1 dr.

The image comes up very rapidly and varies from rich brown to deep black, according to character of negative and times of exposure.

Should there be any tendency of the whites of the picture to overcast by reason of excess of exposure, the addition of tartaric acid to the developer will prevent such clouding.

The tendency from overexposure to veil is prevented altogether by the addition of a small percentage of nickel nitrate to the original coating solution, but while effective in this direction the nickel decreases the sensitiveness of the paper. However, where vigour and brilliancy is desired at the sacrifice of rapidity, the nickel will be found of great advantage, but care must be taken to keep the amount down to a minimum.

JOHN BARTLETT.

\* On this point the following editorial note appears in the "Camera":—"We beg to differ. Our tests with the paper this summer—and probably our difficulty was owing to the extreme humidity—the paper did not keep for any length of time, although in the winter months we had great success and fine prints and the paper kept fairly well.—Eds., B.J."

THE first issue, as a separate publication, of "The Process Engraver's Monthly," late "The Process Photogram," has been published, and contains, we are glad to see, an abundance of matter and a number of supplements, which should be of the greatest interest to the process crafts. There is an example of the Spray printing of the Aerograph Company, particulars of the new etching machine of Dr. Albert, the address of Mr. A. J. Newton at Bolt Court on "The Commercial Side of Photo-Engraving," and lastly an article by Mr. Charles E. Dawson, illustrating a modified method of block making for poster work. We wish our contemporary every success on its new departure.

## COLOUR - FILTERS FOR ASTRONOMICAL PHOTOGRAPHY WITH REFLECTING TELESCOPES.

From the *Astrophysical Journal*.

THE great advantage now taken of photography in recording astronomical data, and the ease with which a visual refractor may be converted to a photographic by means of a colour-filter, have gradually changed and enlarged the methods in telescopic work until there is now practically no branch which can not or could not be better performed by its aid.

The lens of the refractor is corrected for a certain limited spectral region—generally, the yellow green near  $\lambda$  5550, because in this region the eye is most sensitive to slight differences, the remaining hues coming to an approximate focus at varying distances from this point of correction. The function of the colour-filter consists simply

made use of, as in the later methods of photographic photometry. The use of "isochromatic" plates tends but slightly to a betterment for, when we consider that such a plate still remains its maximum sensitiveness to the violet end of the spectrum, then it can be seen that conditions are not greatly improved.

In consideration of the needs of this branch of the work, the writer undertook the preparation of a colour-filter for use with the 24-inch reflector, to be used initially in obtaining negatives for photographic stellar photometry. Briefly stated, the method employed in adjusting such a filter consisted in (1) isolating a few dyes and making of them a special spectroscopic examination, singly

KH G F bE D

Fig. 1.—Comparison of prismatic and diffraction spectrum of diffused daylight.

in absorbing from the incident light all other hues but those for which the lens is corrected.

Strictly speaking, it is not possible to construct a filter which will accomplish this end by itself without very greatly lowering the luminosity of the light transmitted, nor is it necessary to do so. Because of the selective sensitiveness of the photographic plate we are able to divide the work between the filter and plate. If, for example, we select such a plate as Cramer's instantaneous isochromatic, we find a secondary maximum of photographic action which corresponds to the yellow-green of the spectrum; the insensitiveness of the plate (on normal exposure) to red or orange renders it unnecessary to absorb either of these hues by the filter, but only to absorb the ultra-violet, violet, blue, and to dim down the blue-green, the plate itself being but slightly sensitive to this hue.

In the case of the reflecting telescope the necessity for employing a colour filter has not been recognised to the same extent, because of the fact that all the component rays in white light are brought to a focus at the same plane, and it requires but a limited experience to obtain with this instrument a photographic record of telescopic objects which show structural detail far beyond the ability of the eye to perceive.

There is, however, one very serious defect in the photographs thus obtained; that is, an almost exact reversal of colour-luminosity. If we compare the luminosity-curve of the spectrum with the intensity-curve of the ordinary photographic plate, we see in a moment how utterly false and unreliable is the result in so far as colour is concerned. Considered even as a representation of form, it does not conform to the requirements of a "record of fact," because it is quite within the bounds of possibility to conceive of structural detail visible with a hue to which the plate is altogether insensitive.

This discrepancy between the visual luminosity and photographic intensity is very evident in the case of direct stellar photography, which becomes considerably worse when "extra-focal" images are

KH G F bE D C B

Fig. 3.

Figs. 2 and 3.—Daylight diffraction spectrum, with varying exposures, approximating the visual luminosity-curve: 2. Pinacyano-plate and filter; 30s to 30m. 3. Trichromatic plate and filter; 15s to 8m.

and in combination; (2) coating trial filters with carefully measured amounts of gelatine containing known amounts of dye and estimating the approximate density of the spectrum as photographed through this filter against the normal luminosity-curve; (3) coating the optical glass with the amount of dyed gelatine as thus determined and measuring the density of the spectrum negatives taken through this screen; (4) photographic determination of the absorption at various exposures, and of the exposure increase.

From knowledge gained by a somewhat extended experience in making a large number of filters for various purposes, the following dye-stuffs were selected, estimated as being fairly near to the absorption required, viz.:—

Tartrazine,  
Auramine O.,  
Metanil yellow S.,  
Nitrosodimethylanilin.

From these dyes colour-wedges were now prepared. A solution was made of

Gelatine (Fischer and Schmidt—extra hard)	2.5 grams.
Distilled water	100.0 cc.
Dye	0.25 gram.

Seven cc. of this solution at a temperature of 55 degrees C. was flowed upon a plane glass strip 50 by 250 mm., and then laid aside to set in a drying-chamber, with one end raised to a height of 5 mm. from the horizontal plane of the support, thus causing the gelatine to flow slowly toward the lower end. When dry a plane cover-glass was cemented on with Canada balsam and the edges bound. A cm. scale was then ruled upon the glass with a writing diamond, and a series of spectrograms made showing the absorption at every cm. for constant exposure.

U CYGNI.

Fig. 3A.—On Seed "27" plate, without filter.

Fig. 3B.—On Cramer "Trichromatic," with filter.

At this point it may be well to note the entire unsuitability of the prismatic spectrum for work of this nature. What we are concerned with principally is the rendition of the relative spectral luminosity—the dispersion is of no moment, provided it be sufficient to allow of the spectrum being easily read. The difficulty comes in the interpretation of prismatic results. We have, of course, the various dispersion formulæ by Helmholtz, Ketteler, Cauchy, Hartmann, and others, but for work of this nature they are of no value whatever, because they do not take into account the absorptive effect due to density and composition of the glass composing the prism itself as it influences the luminosity. For example, supposing that a particular prism is of such a density and absorption that with normal exposure it gives a negative in which the ultra-violet is only impressed to  $\lambda$  3900, then there is no formula which can supply the photographic intensities of the shorter wave-lengths to which the plate is normally sensitive, while the absorption even throughout the visible portion is still an unknown quantity and

varies with every change in the refractive index. As an illustration of this want of reliability, Fig. 1 shows the influence of this absorption in the comparison between the prismatic and diffraction spectrum, in which the lack of concordance may be readily seen.<sup>1</sup>

In all of the spectrographic work, therefore, use has been made of a replica grating of 15,150 lines to the inch, with the collimator directed at a constant angle to the northern sky, and illuminated by diffused light.

Fig. 5.—Increased exposure through No. 26 of Tartrazine wedge, showing transmission of ultra-violet.

Fig. 6.—Portion of spectral record of Aesculin wedge.

HK G F BE D  
Fig. 1.

The function of the colour-filter is to reduce the preponderance of action in the blue and violet region of the spectrum and absorb entirely the ultra-violet. The transmission throughout the remainder of the spectrum should be undimmed by any absorptive action due to the dye.

Examination of the negatives from the wedges, as above outlined, shows that in the dye tartrazine (Badische Aniline and Soda Fabrik) we may obtain the first component of the filter sought for. Fig. 4 shows the record of this colour-wedge, in which the ultra-violet transmission will be noted as extending down even into the dense end of the wedge. This transmission, which is masked by the absorption in prismatic spectra, becomes painfully apparent when the exposure is increased or the light rendered more intense, as is shown in Fig. 5. Such a record serves the very useful purpose of showing the danger in the use of this much-vaunted dye for trichromatic and orthochromatic colour-filters, even when used in extremely concentrated form. It will be observed that in scale

<sup>1</sup>For the prism used  $\mu_D = 1.6094$ .

No. 17 of this record the excessive density in the blue of the spectrum from F to G is well corrected for; but the violet is still too strong, and the ultra-violet is of course transmitted. Another colour-wedge made of

Gelatine .....	2.5 grams.
Water .....	100.0 cc.
Aesculin .....	0.2 gram.

shows that at scale-number 23 or 24 we have an absorption corresponding to the requirements necessary for the second component of the filter — viz., absorption of the ultra-violet with a gradual absorption in the visible violet. (Fig. 6.)

The two colour-wedges are now superposed upon one another with the selected scale-numbers in agreement and an exposure then made through the combination, which gave a result closely approximating the effect sought for. All preliminary exposures and records are made on Cramer "Instantaneous isochromatic" plates, which have a comparatively low sensitiveness to the blue-green about  $\lambda$  5050, for which due allowance must be made in the interpretation of the spectroscopic records. It will be evident that any absorption of the dye in the blue-green region would be instantly detected in the photographed spectrum.

Arrived now at a satisfactory point in the trial exposures, the next consideration is the production of a filter which will possess the same absorptive action as do the combined colour-wedges at the points selected. Monpillard<sup>2</sup> has suggested a method for obtaining this result, which consists in measuring the thickness of the colour-wedge at the selected point ( $e$ ) and using this as one term of a simple proportion. Two other terms consisting of thickness ( $a$ ) and weight of dye-stuff ( $d$ ) are obtained by coating a separate plane glass of known area with a measured amount of dyed gelatine; the amount of dye necessary for the finished filter ( $x$ ) is then to be found from the simple calculation,

$$\frac{e}{e_1} = \frac{d}{x} \quad \text{or} \quad x = \frac{e_1 d}{e}$$

This method commends itself by its simplicity, but in the hands of the writer it has not proven suitable. Presumably, if the thickness of the film on the colour-wedge at the selected point were measured more delicately than in the method adopted, say, in the interferometer, then a much closer approximation might be arrived at than has been possible when using a Brown and Sharp micrometer caliper. As it was, the critical adjustment of a filter is so delicate that a minute quantity of dye, either in deficiency or excess, is fatal to correct performance. The making-up of a large quantity would also tend to reduce error, but for the manufacture of a single filter of special absorption such a course is not practical.

By a method of trial and error we may, however, very speedily arrive at an extremely satisfactory duplication. A plate of ordinary glass of exactly the same size as the desired filter is taken, and upon this is flowed a measured amount of the same solution as was used in making the counter-wedge. This amount is approximately determined by visual observation, while in contact with a white surface on which also rests the wedge.<sup>3</sup>

R. J. WALLACE.

(To be continued.)

STUDIO FIRE in Belfast.—A fire broke out one day last week at the studio of Mr. William Abernethy, Donegall Place, Belfast. Most of the damage was in the rear portion of the building, which has a corrugated roof. The frontage in Donegall Place was not seriously affected. The studio, it may be mentioned, is, or was, up till the fire, a beautiful one. It was opened four years ago by the Countess of Shaftesbury, and is a model of comfort and perfection in equipment. On Thursday evening some of Mr. Abernethy's employees were engaged in the studio noting pictures with a view to arranging which of them should be sent to the International Exhibition in Dublin in 1907. When they left all was secure, and there was no sign of fire. Most of the damage was in the reception, dressing, store, and work rooms, but the entire loss is covered by insurance.

<sup>2</sup>Comptes Rendus, 141, 31—33, 1905.

<sup>3</sup>This method has been adopted after various trials with instrumental methods (colourimeter, tintometer, etc.) for taking into account the shade change in drying, no greater reliability could be obtained.

## DEATH OF MR. THOS. R. DALLMEYER.

ON Christmas Day one of the best known members of the photographic world passed away, after an illness of only five days. Thomas Rudolphus Dallmeyer was the second son of the late John Henry Dallmeyer, and was born in May, 1859, his mother being the daughter of that celebrated optician, Andrew Ross. After several years at private schools he went to Mill Hill School, under Dr. Murray, the now famous lexicographer. After leaving Mill Hill he became a student at King's College, London, where he took his B.Sc., London, devoting the greater part of his time to those mathematical studies which he turned to such practical account in later years. At the same time he was doing a considerable amount of actual mechanical work in his father's factory grinding lenses and making

The late Thos. R. Dallmeyer

optical brasswork, under the guidance of the late Mr. Judd. On the breakdown of Mr. J. H. Dallmeyer's health in 1882, he was ordered to take long sea voyages, and Mr. T. R. Dallmeyer then assumed the control of the business, in which he was actively interested, until his death. During his career Mr. Dallmeyer designed many new and valuable instruments, but his name is more intimately connected with telephotography than with any other branch. He made the first practical telephoto lens in 1891, and hardly a year passed in which he did not make some modification or improvement, his latest work being in connection with the Junior "Adon." Among his other inventions may be mentioned a rapid triple cemented landscape lens, a rectilinear landscape lens, the original naturalist's camera, and many special lenses for cinematography and other purposes. For many years, too, Mr. Dallmeyer had occupied himself with cameras for colour photography, though he never reached a result which satisfied him. This aim was at a one-exposure three-colour camera. He became a member of the Photographic Society of Great Britain in 1886, and was in succession member of Council, vice-president, and president (1900), taking a prominent part in a perturbed period of the society's history.

Physically, Mr. Dallmeyer was a well-built man, above the average height, and far from suggesting the delicate state in which his health

had been for several years. In his youth he was an accomplished athlete and a fine boxer, and in later days an enthusiastic gardener and a Fellow of the Royal Horticultural Society. He had a singularly winning manner, and was generous to a fault. Many a struggling genius has received substantial and too often unappreciated assistance from him. His loss will be deeply felt, not only by his photographic friends, but also in the wide literary and artistic circles in which he had for years been a familiar figure.

Our portrait of the late Mr. Dallmeyer is a reproduction of the painting by Sandys

#### DEATH OF MR. J. T. SANDELL.

WE are sorry to have to announce the death of Mr. J. T. Sandell, which took place at Catford, where Mr. Sandell had been residing for some time, on Saturday last, December 29. As readers of our columns know, the deceased gentleman had been in a very serious state since the early part of last year. The doctors had given up hope of his recovery, yet recognised that years might elapse before the disease proved fatal. Their anticipations, however, were not fulfilled, and the patient's life reached a termination, which, under the circumstances, was a merciful one, on Saturday last. Mr. Sandell, from his long association with the dry plate trade, was one of the most familiar figures in photographic circles. He commenced his career in the establishment of Messrs. R. W. Thomas and Co., in Pall Mall, and when the Thomas works were removed to Thornton Heath became manager and chemist. There he brought on to the market the "Thomas" plates, the lantern plate particularly having a large share of public favour. He also introduced, through the same commercial channels, the "Sandell" double-film and triple-film plates, the principle of which he afterwards embodied in the "Cristoid" film, brought out by the Sandell Dry Plates and Films Company, Ltd. Mr. Sandell was more at home in the laboratory and behind the demonstration table than in the direction of business enterprises. His exhibitions to photographic societies of the properties of his patented films were models of technical demonstrations. His generous and somewhat impulsive disposition made him many friends and few enemies; and he will be missed from the ranks of his intimate associates, as well as of the public who knew him as a lecturer and demonstrator, with sincere regret.

#### DEATH OF MR. GEORGE BISHOP.

MR. GEORGE BISHOP, senior, partner in Messrs. Marion and Co., Ltd., died at his residence, Ashley Gardens, London, S.W., on December 28. Mr. Bishop, who was seventy-two years of age, had relinquished active interests in the business, of late years, to his brother, Mr. Frank Bishop. His decease will, however, be felt by a large circle of friends.

#### MICRO-PHOTOGRAPHS AS MAPS.

A DESCRIPTION of the use which is being made of micro-photographs for minute and portable reproductions of maps is given in the "Scientific American" by Dr. Alfred Gradenwitz, who describes the invention of Dr. Vollbehr, of Berlin, by whom micro-photographs have been applied to military purposes.

Microscopic transparencies 4 to 5 centimetres (1.574 x 1.968 inches) in size are used in place of large maps. These represent a map of the Etat Major drawn to the scale of 1-100,000. They are inserted between two glass binding plates, so as to form a lantern slide. In front of the transparency there is a lens capable of being adjusted for any eye by turning it either to the left or right. No other eye-glass should be used in connection with the lens. The latter is fitted in a small frame susceptible of a vertical and horizontal displacement, so as to enable any point of the transparent map to be brought immediately in front of the eye, 175 square kilometres (67.56 square miles) being inspected with each position of the lens. The minute map is divided into squares at distances of 2.5 kilometres (1.55 miles) each, the squares being numbered horizontally at the top of the map and marked with letters in a vertical direction, thus enabling any given point to be traced readily. The slides are loosely

in the holder, and they can be exchanged at a moment's notice when ever another map is to be examined.

If the lens is used in the daytime, it should be held with the handle in front of the eye, when an intensely illuminated image of the map will be obtained, so that even the smallest lines and most minute marks will be readily distinguished. For use at night an especially designed illumination box is added, including small electric light similar to the familiar "ever-ready" lamps. This box can be attached to the back of the apparatus, where it is held in place by small clips. By pressing a button a small glow lamp is lighted. This lamp illuminates the transparent map about as intensely as does daylight, and thus the lamp can be used in dim weather if more light is needed.

#### AN INTERVIEW WITH SANTA CLAUS, LTD.

As we speed upwards through the chill air and the damp clouds we look down upon slushy snowy London. Through the translucent roofs of the studios we can see fair heads becoiled with silken tresses bending over busy fingers retouching for dear life, so as to get the Christmas orders out before they are countermanded for being overdue. When we alight at the portals of Santa Claus, Ltd., now an immense concern with distributing facilities unmatched in Europe or America, our editorial card at once admits us to the presence of well-known, highly-complexioned, jovial-faced benefactor, who, until recently, made his nocturnal and personal visits to babes exclusively, but who now acts as managing-director only, and extends his supplies to deserving people of all ages.

"Busy this season?" we ask.

"Not the word for it, my boy."

"And what of camera folk particularly?"

"Well, they've all had fat stockings. I was most particular in seeing that they all had suitable and useful presents."

"What superb generosity! The editors of the photographic press, for example, How did they fare?"

"Why, if I remember rightly, we sent Mr. Br\*\*n a—"

"Never mind him. What did you give to Mr. H\*rs'l'y H\*nt\*n?"

"Let's see, The A.P. Why, we gave him a nice box of dress ties, with a glass lid, a hand mirror, and a tin trumpet."

"And Mr. Sh\*wd\*n W\*rd?"

"My literary staff indited one or two congratulatory paragrams on his new Process Monthly."

"Excellent! And what to Mr\*t\*m\*r?"

"Mr. M\*t\*m\*r had a fountain PN. It hadn't a nib; but as he only carries those things for show, he won't notice that fact. We thought of scissors. He wears those out at such a rate, however, so we sent him a derrick."

"I see, for lifting. Now about Mr. Ch\*ld B\*y'l'y?"

"He had a copy of the new work called 'The Complete Editor; or Pseudonym Secrets.'"

"How nice of you! Then there's the Rev. F. C. L\*mb\*rt."

"Yes, he had 'How to Succeed though Good,' and 'The Lives of the Saints,' illustrated by Mrs. Barton."

"You think of everything! Any journalistic celebrities come in for anything?"

"Oh, rather! To Mr. Newton we gave a beautiful little tract upon the effect of illegitimacy on three-colour work. Mr. Douglas English had some rat poison, some fly-papers, and a ginn trap. Mr. Rawlins had a 7lb. tin of printer's ink and a pair of boxing gloves; M. Demachy, a box of oil colours and a rapier. Mr. Tilney had a box of paints too, and a Sandow developer."

"Good! and how about Russell Square?"

"Well, Mr. Secretary Mac. we thought would like a box of crackers. He uses the coloured gelatine off them, you know; and then we remembered that he was a Scotsman, so we dropped him down a bottle of Johnny—"

"Any amateurs?" I interrupted.

"Only Mr. Coburn, and to him we gave a new lens, an exposure meter, and a watch."

"You couldn't have suited him better; but they'll quite spoil his reputation, I'm afraid. And that's all, eh?"

"Enough 'too!'"

"Well, where do I come in."

"You don't!"

So I went out.

## Photo-Mechanical Notes.

### Etching Machine for Half-tone and Line Plates.

AN addition to the means of affording mechanical aid to the etching of metal plates in the making of line and half-tone blocks is advanced in a recent patent specification (No. 20,321) by H. G. Bartholemew, 16, Westminster Palace Gardens, S.W., and H. M. Bussey, 28, Bonnerville Road, Clapham, in the form of an apparatus designed to plunge the plate to be etched rapidly into the etching fluid, and to remove it at once, this sequence of actions being repeated as long as

power is supplied to the mixture. As seen in the figure, the plates, fastened face downwards in the frames *r*, are covered on the extremity of a plunger, to which an up and down motion is communicated by the eccentric gearing *g*. The acid is contained in a chamber which is closed when the machine is working, but into which the plates are introduced by the doorway *k*.

### Machine Printing of Intaglio Etched Plates.

A patent has been granted to an American engraver, S. L. Morgan, of 112, Home Avenue, Rutherford, Bergen County, New Jersey, for a machine for the printing from plates engraved in intaglio, and therefore requiring to be wiped, so as to remove the excess of ink, between the taking of each impression. The constructional details of the machine are too minute to be explained without the reproduction of the fifteen figures in the specification, and therefore this latter (No. 14,565, 1906), should be consulted. It may be said, however, that:—

The wiper for the printing surface is in the form of a flexible strip which is first moved in one direction over the printing surface, and is then returned, so that the succeeding wiping operation is by a soiled portion of the strip.

The wiping operation commences with a much soiled portion of the strip, and finishes with a less soiled portion of the strip.

There is a strong flexible belt moving with and supporting the wiping strip.

### The Penrose Process Pocket Book, 1907.

This little pocket book and diary contains not only the usual blank spaces for daily notes; but also a collection of useful formulæ and tables for process work. It is compiled on the same lines as in previous years, but the formulæ and tables have been thoroughly revised and brought up to date. The price, from Messrs. A. W. Penrose and Co., 109, Farringdon Road, London, E.C., is 1s. 6d., in leatherette, or 2s. in full leather.

The following patents were applied for recently:—

**LINE-BLOCKS.**—No. 28,200. Improvements in the production of letterpress line-blocks, without the aid of photography, direct from sketch. James Will, 11, Liverpool Street, London.

**ETCHING.**—No. 28,679. Improvements relating to etching. Johan Atel Holmstrom, 111, Hatton Garden, London.

The following Complete Specification is open to public inspection before acceptance under the Patents Act, 1901:—

**ETCHING.**—No. 28,679, 1905. Holmström.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between December 17 to 22:—

**CHANGING BOXES.**—No. 28,868. Improvements in changing boxes. Edouard Streiff, France. (A. J. Boulton, 111, Hatton Garden, London, E.C.).

**PRINTING FRAMES.**—No. 28,936. Improvements in printing frames. Henry Major, 24, Carholme Road, Forest Hill, London, S.E.

**DEVELOPING TANKS.**—No. 29,064. Improvements in photographic developing tanks. Ernest Elder, 88, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**PHOTOGRAPHIC MOTOR CARAVAN.**—No. 18,345, 1906. The claim is for a vehicle for the conveyance of photographic apparatus and a dark-room, and provided with an electric battery adapted to

drive an electro-motor for propelling the vehicle and to feed electric lamps for illuminating the objects to be photographed. Jean Schmidt, 10, Kaiserstrasse, Frankfurt-on-Main, Germany.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Where to Go

In the heart of the Franconian part of Bavaria (writes Mr. Jas Shaw in "Photography") lies Rothenburg o/d Tauber, one of the finest mediæval towns to be found in the Fatherland. For a quiet, restful holiday I know no better place. Fortunately for the artist and the photographer, Rothenburg has largely escaped the hand of the restoring vandal, and still presents a variety of quaint buildings and fascinating streets, which form a perfect mine of pictorial wealth.

Set high on a hill above the lovely valley of the River Tauber, the old red city is still encircled with massive walls, from which at short interval spring towers of all shapes and sizes, and with here and there huge embattled gateways commanding the entrances to the town. Through the gates, especially in the morning and evening, a constant flow of picturesque life is passing.

### Light-hearted Russell Square.

"The Amateur Photographer," in its notes by the "Magpie," asks: "Should a learned discourse be more serious than a police court case? If the sciences of phrenology and of palmistry may be allowed their funny moments, why not also photography? Anyhow, whether it be right or wrong, this is the kind of thing that we have arrived at:—Scene: A lecture-room. Technical bouncer (to demonstrator who is developing a print in a quarter-plate dish): 'Can your process

be worked up to 36x24." Demonstrator: "Not in this dish." (Roars of laughter.) Chairman (summing up discussion): "I always sensitize the paper overnight at my bed time." Voice from audience: "You mean same morning." (Laughter.) Chairman (continuing): "And leave it to dry in the kitchen; but the 'missis' won't let me use that room in the daytime, so I fall back on the scullery." Voice: "Why not take the pledge?" (Laughter.) Chairman continues: "To reduce over-intensity I use soap—any kind which comes handy." Voice: "Is that why your prints are sometimes mottled?" (Prolonged titter.) Chairman: "When I said any kind, I should have added—excepting trust soap." Audience falls into risible convulsions. Thus do the destinies of a new process kick the balance with Plowdens'isms."

### Bordered Postcard at One Printing.

If we place a film negative in the printing frame with a piece of clear glass as usual, then put a postcard on top and print, we will get writes Mr. J. Peat Miller in the January "Photographic Monthly," our picture with a black border larger or smaller according to the size of the film; but if we take a piece of white paper and cut an opening about the size of the film (either larger or smaller), then put that into the frame and centre the film over the opening, then put in a card and print as usual, we get our picture with a light or dark grey border, according to the thickness of the paper and the printing density of the negative. If the opening in the white paper is smaller than the negative, we will get a narrow white border next the picture, and if the opening is larger than the negative we get a narrow black border next the picture, and the broad grey border outside of that.

The effect got in this manner resembles a print mounted on a natural tint mount. If we want a darker tint we use a thinner paper, or two sheets of the same paper will give a lighter tint.

### Stains on Gaslight Prints.

In many cases out of ten brown stains on gaslight papers (writes Mr. G. Lewis in "Focus") are due to the prints not being kept on the move in the fixing bath. If they stick together, or float on the top with the surface exposed to the air—if, in fact, they are not surrounded with hypo solution—stains are inevitable, and they cannot be removed. Hypo brought back by the fingers into the developer will also produce them. Stains may also occur with some papers if the hypo bath is not made acid when directed. The simplest plan is to keep a special bottle for the acid solution (acetone sulphate, tartaric acid, or sulphate of soda and sulphuric acid), adding a little to the ordinary fixing bath when required. It may also be used on plates and lantern slides, but it will be fatal to P.O.P.

## New Apparatus, &c.

The "Euryplan" f/4.5 Anastigmat. Sold by A. E. Staley and Co., 29, Tavistock Inn, London, E.C.

Messrs. A. Staley and Co. have submitted one of these new lenses to us for examination. It is a symmetrical objective, each combination consisting of three lenses with an air space. Three series are listed, with respective full apertures of f/4.5, f/5.6, and f/6.8. The one we have tried is of 5 in. focal length, and aperture f/4.5, and at full aperture it seems to cover a quarter-plate most perfectly. The astigmatism and the coma are both small and practically negligible, while the field is very nearly quite flat for a moderately distant object. The lens is of somewhat narrow angle, the extreme angle being about 63 deg. It will therefore just cover a 5 x 4 plate, and though it covers this size with excellent definition the requirements of rising front, etc., suggest that it is best adapted to a quarter-plate camera. The single combinations will, of course, cover a larger plate, and they do so with good definition if stopped down. The price of the lens (£5) is moderate, considering its extreme rapidity, and it should be a very valuable lens for focal plane work. This is the second f/4.5 lens we have had to report upon lately, and it is evident that focal plane workers are being especially well catered for just now. Not very long ago lenses such as these were quite unattainable, and even up to quite recently they could only be procured at very long prices. Their narrow angle we consider to be an advantage, for the matter of covering power has been

considerably overdone of late. A big angle has advantages when the rising front is used, but the rising front is very seldom used to extremes, and the wide angle tends to fog the plate. It is not worth

while fogging every plate exposed for the sake of providing a movement that may never be required.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### FRIDAY, JANUARY 4.

Hampstead Scientific Society. "Some Missing Links in the Plant World." Miss Marie Stopes, D.Sc. (Lond.) Ph.D.  
West London Photographic Society. "Cruise in the Western Mediterranean." G. Lamley, F.R.P.S.

#### MONDAY, JANUARY 7.

Leek Photographic Society. "A Visit to a Pottery." Thos. Hantley.  
Southampton Camera Club. Annual General Meeting.  
Blackburn Camera Club. "Up the Moselle with a Camera." W. Phillips.  
Bowes Park Photographic Society. Lantern Slide Competition.  
Lancaster Photographic Society. "Carbon." Demonstrated, Messrs. H. Engleworth and Co.  
South London Photographic Society. "A Dive into Belgium." W. L. F. Wastell

#### TUESDAY, JANUARY 8.

Royal Photographic Society. "The Action of Substances upon the Latent Image." C. E. K. Mees, D.Sc., and S. E. Sheppard, D.Sc.  
Darlington Camera Club. "Flowers and Fruit Studies." E. Seymour.  
Leeds Photographic Society. General Meeting. New Lantern Slides. Godfrey Bingley.  
Worthing Camera Club. Prize Slides, kindly lent by Photography, with Criticism.  
Sheffield Photographic Society. "A Contribution to the Discussion of the Relation of Photography to Art." Henry W. Dick.  
Burton-on-Trent Natural History and Archaeological Society. "A Comparison of Developers." H. Lloyd Hind, B.Sc., A.I.C.  
Blyth and District Camera Club. "Bromide Enlarging." A. D. Miller.  
Hackney Photographic Society. "Enlarged Negatives." Rotary Photo. Co.

#### WEDNESDAY, JANUARY 9.

Edinburgh Photographic Society. "Motives in Art as Illustrated in the Works of the late George Frederick Watts, R.A." Alexander Eddington.  
Borough Polytechnic Photographic Society. "The Making of Enlarged Negatives with Rotograph Negative Paper." Rotary Photographic Co., Ltd.  
Croydon Camera Club. "Theory and Practice of Self-Toning Papers." J. J. Griffin and Sons.  
Covese Camera Club. "Hford Lantern Plates." A. Brooker.  
Evertton Camera Club. "Self-Toning Papers." J. J. Griffin and Sons.  
Bristol Photographic Club. "Bayeux Tapestry." W. T. Crank.  
Woodford Photographic Society. "Manipulation of Apparatus." W. L. F. Wastell, F.R.P.S.  
Leicester Photographic Society. "Sports and Pastimes with the Goerz-Anschutz Folding Camera."  
South Essex Camera Club. "What Can be Done with a Hand Camera." C. P. Goerz.

#### THURSDAY, JANUARY 10.

Blenheim Club. "The Abbeys of the Cistercians." C. H. Bothamley, F.I.C.  
Rugby Photographic Society. "The Photographic Lens." C. P. Goerz.  
L.C.C. School of Photo-Engraving. "The Artist and the Advertiser." J. Murray Allison.  
Hull Photographic Society. "Architectural Photography." J. R. Wigful, A.R.I.B.A.  
Liverpool Amateur Photographic Association. "The Amateur Photographer and the Professional Astronomer." Rev. Father Sidgreaves.  
Richmond Camera Club. "Pinatype Process." Fuerst Bros.  
South Norwood Photographic Society. "Enlarging on 'Rotograph' Bromide Paper, including a Chat on Toning Bromide Paper."

BOMBAY BRANCH OF THE P.S.I. On December 3 in Mr. Vaughan's quarters attached to the Bombay Paper Currency Office a meeting of the general committee of the proposed Bombay Branch of the Society of India was held, when Mr. C. Lynde, the secretary, explained the position. There were not sufficient members enrolled to enable them to constitute a branch of the parent society at Calcutta, therefore it was deemed desirable to constitute a local body. Hitherto only thirty-two gentlemen had been forthcoming; nearly double that number was required to commence practical operations, and to meet the expenses. A fund was proposed to be started; a constitution required to be framed. It was decided that after these preliminaries had been carried into effect a meeting should be called at a convenient date to ratify the rules.

## Commercial & Legal Intelligence.

CHARLES TYLER AND ENGLAND BROTHERS, LTD.—£10,000 5 per cent. debentures, created and dated December 6, 1906, have been registered. Property charged: The company's undertaking and property, present and future, including uncalled capital. No trustees.

### NEW COMPANIES.

H. BOWN.—Capital £20,000 (£1) (5,000 6 per cent. cumulative preference). To adopt an agreement with H. Bown for the acquisition of the business of an artist and photographer, carried on by him at 29, Stockwell Park Road, S.W.; 43, New Kent Road, S.E.; 31-33, Jamaica Road, S.E.; and 298, Clapham Road, S.W. Minimum cash subscription, 10,000 shares. First directors: R. Corfield, T. Grimes (managing director), and J. S. Reid, 250 shares. Remuneration (except managing director), £100 per annum. 23, Great St. Helens, E.C.

W. GRIGGS AND SONS (1906), LTD.—Capital £8,000, in £1 shares. Objects: To acquire the business carried on by W. Griggs and Sons, Ltd., and to carry on the business of photo and chromo lithographers, chromo collotypers, colour process, and half-tone engravers, photo-etchers, stationers, printers, electrotypers, photographic printers, etc. No initial public issue. The first directors (to number not less than two nor more than seven) are: Carl Hentschel, A. T. Clarke, and W. Griggs. Qualification, £100. Remuneration as fixed by the company.

## Correspondence.

*\*\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*\*\* We do not undertake responsibility for the opinions expressed by our correspondents.*

### THE MEASUREMENT OF BUILDINGS FROM PHOTOGRAPHS.

To the Editors.

Gentlemen,—Just a warning note to those of your subscribers who may be tempted by Mr. Lockett's interesting paper on "Elementary Photographic Surveying," to try their hands at a first attempt. In London and the South country, bricks and buildings are generally four courses to a foot, but in the Midlands and the North, and in many engineering structures in London and neighbourhood four courses measure 13 inches. Further, more than one building of prominence in London is built with 2-inch bricks. Consequently a certain degree of caution should be exercised in using a photograph of bricks in a building as a scale.

From a point of view of accuracy two photographs from the ends of a measured base and with known bearings are much to be preferred.—Yours faithfully,

HARVEY COLLINGRIDGE, B.Sc., A.M.I.C.E.

55, Hornsey Rise Gardens, Crouch End, N.

December 29, 1906.

### THE CONVENTION SOCIAL.

To the Editors.

Gentlemen,—Judging by several letters recently received, it would appear that some of the invitations to the above function, which were posted December 15, have not been delivered.

Should any of your readers, who are members of Conventions, not have received my circular, I shall be glad if they will kindly communicate with me at once.—Thanking you in anticipation, I remain, Gentlemen, yours truly,

F. A. BRIDGE,

East Lodge, Dalston Lane, London, N.E.

December 29, 1906.

### A PHOTOGRAPHIC ASSISTANTS' PROTECTIVE SOCIETY.

To the Editors.

Gentlemen,—I am very pleased to announce that 22 more have sent in their names. This makes the total of 93 members. I have also replied to 72 others who have written to me.

To my surprise I find a great number of applicants who never read the Journal; they rely upon some passing friend to tell them what is going on in their own profession. To place oneself out of touch of all the best that can be procured in the profession shows very poor policy on the part of a great many assistants. No one can say that a week passes without being able to derive some good from the Journal, and I fail to see that it is twopenny ill spent. Two members have sent me small sums towards any expenses incurred by me. These I have returned with thanks. I must strongly point out that, on no consideration, must money be sent to me for this purpose. The only thing that I require are members and suggestions. I have borne the brunt of it so far, and am quite prepared to go on with the cause and bear the remainder. Those who require a reply need only send a stamped addressed envelope, and, sooner or later, I will reply. My correspondence has been rather lengthy and heavy of late, but I am more than repaid by the steady increase of members and suggestions. Two only have sent suggestions. One is from a manager, who has no doubt given a good deal of thought to the matter. The suggestions are:

(1) "That the P.P.A. start a separate society for assistants of all grades. Yearly subscription to be 5s. The assistants could then become associates of the P.P.A., thus giving them a chance to show they are connected with the P.P.A. The subscription would then defray any expenses connected with publishing quarterlies, or what the P.P.A. thinks appropriate. The bona-fide managers of firms could then act on the committee of the associates, to bring forward all grievances, and any points which would better the assistant's career. Assistants could then be put on a sound basis in all grades of the profession. I maintain that the assistants could do as much then towards bettering their employers as well as themselves. The system of examinations could still be carried out, and, with the aid of the assistants' subscriptions, could be managed better and more expeditiously. This system would eventually make a stronger bond between employer and employee. As a manager, I shall be willing to act on any committee that is formed."

(2) "To form a society of photographic assistants to work in conjunction with the P.P.A., to have a separate page set apart in the Journal for assistants' correspondence, and any articles they would like to write on the subjects of assistants and photography."

As regards having a page set apart in the Journal, that rests with the assistants. If they would only show some enthusiasm in their profession I have not the least doubt that our highly respected editors would offer every opportunity. If the assistants follow in the same tracks as they have been doing, then it would not pay to set a page apart for that.

I am still open to receive names and suggestions, but before I place any suggestions before the P.P.A. I hope to be able to place a list of 350 names before them, then one would have some heart in asking the P.P.A. to offer some helpful suggestions to the society we are trying to form.

Our thanks are due to the editors for so kindly placing so much space at our disposal with much apparent willingness.—Yours faithfully,

19, Richmond Terrace, Romsey, Hants.

V. DOUST.

### PYRO-AMMONIA DEVELOPER.

To the Editors.

Gentlemen,—I must differ with the paragraph in "Ex Cathedra" in the B.J. of December 21. Almost every sentence in it is contrary to facts and truth. I would not like to enter into discussion on this subject, but I will only say the following facts in answer to the rash assertions.

I do not understand what you mean exactly by rapid oxidation of pyro-ammonia developer, but I have been using it now for dry plates—gelatine, of course—for about 26 years or more, having developed some of the very first plates made with it, and use it yet, with good results, however not so good as originally, and that means

since A.D. 1900, when extra rapid plates came into use and the rage. I make up solutions of pyro and ammonia bromide, and use it as long as six months. The ammonia solution (put out of court, as you say) I keep easily for months in a glass stoppered bottle. I never used a hydrometer; in fact, never needed one, having no use for it. In development, when exposure was correct, of course, developing four negatives was an easy matter, and I reached as much as six negatives in the same developer, and even found that the first negative came up slower than the following ones, up to the fifth, when the development was rather slow. The same was happening with fixing, when the first negatives fixed slower than subsequent ones. As to developing two or more negatives exactly alike, I never tried it, therefore cannot say; but I do not know in how far this can be done to-day with other developers, this not being always the case with stereotypes. I have developed hundreds, and even thousands, of negatives before the year 1900, and always had with the very same pyro-ammonia developer clear, bright, and perfect printing negatives, but for some unexplained reasons the clearness and freedom of stain in film I can no more obtain since that date, specially with rapid plates, but can do so yet with comparative slow plates, H. and D., 120 or less. This same developer I can also use for slow development, taking from two to ten hours. The smell is really not so offensive as a London fog, and at one foot from the dish cannot be detected, as I sometimes even think I forgot to put it in the dish, and I must come much nearer to smell it.—Yours very truly,

A. LEVY.

4, Avenue Pinel, Asnières (Seine).

[If, according to M. Lévy, almost every sentence in our note is contrary to facts, it appears to us that our correspondent's 26 years' experience has given him a poorer opinion of pyro-ammonia than we hold, for not a few of the sentences referred to drew attention to the good, and, for some purposes, unique qualities of the developer. As regards its defects, we still hold the opinions expressed in our note. M. Lévy evidently uses an ammonia solution of very uncertain strength. There can be no possible advantage in this, and if he will adopt our recommendation with regard to the use of an hydrometer he will have a great deal of time and trouble and secure evenly uniform results far more readily. Our remarks with regard to oxidation, of course, applied to the mixed developer, not to the stock solutions. A mixed pyro ammonia developer, in our experience, rapidly acquires a thick oily scum of oxidised pyro, whereas a properly compounded pyro-soda developer is comparatively free from this defect, even when in use. In the case of the former developer, we should certainly always advocate fresh developer for each plate. We also have used this developer for prolonged development, but consider it to be about the most inconvenient one for the purpose, unless the citrate method is adopted, in which case it is probable that the solution soon ceases to be a developer and becomes an intensifier. M. Lévy's experience that the first plate developed of a series comes up more slowly than later ones appears to us simply to illustrate the uncertainty of the developer. The first dose of ammonia was probably weaker than the subsequent ones. Even with accurately adjusted solutions it is difficult to regulate the amount of ammonia used if the stock solution is strong, while weak solutions dilute the developer at every addition.—Eds. B.J.]

THE Royal Photographic Society announces that an exhibition of photographs by members of affiliated societies will be held at 66, Russell Square, London, W.C., from Thursday, January 3, to Saturday, February 23. The exhibition will be open to the public daily from 10 a.m. till 5 p.m., on presentation of visiting card.

THE Bolt Court School.—The annual supper of the students at the Bolt Court School of Photo-engraving and Lithography was held on December 28. Mr. Nelson-Dawson was in the chair, and the Principal (Mr. A. J. Newton) and the Head Art Master (Mr. Cecil Rea) in the vice-chairs. Among the guests were Messrs. W. Gamble (Messrs. Penrose and Co.), Mr. Sparling (Messrs. Hunter's, Ltd.), Mr. George E. Brown (THE BRITISH JOURNAL OF PHOTOGRAPHY), and Dr. C. E. K. Mees. An excellent programme of music was offered, including a play, which is a feature of the Bolt Court suppers. Mr. R. C. Armour this year presented an Assyrian rhapsody, "in two rhaps." the performance of which was highly appreciated by an audience which cheered to the echo.

## Answers to Correspondents.

- \*\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \*\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \*\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \*\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- F. Heyworth, 100, St. Andrew's Road, St. Anne's-on-the-Sea, Lancs. Three Photographs of the St. Anne's-on-the-Sea Lifeboat with Crews.
- The Carbonora Company, 4, Wild Street, London Road, Liverpool. Photograph entitled, "Daddy's Pipe."
- R. Thirlwell, 21, Bridge Road, Stockton-on-Tees. Photograph (Flashlight) of Hartlepool Amateur Theatricals. Two Photographs (Flashlight) of Stockton Amateur Theatricals.

J. R.—The specimens are all good average work. We should say you are worth more than you are getting, but we cannot, of course, speak with certainty, as we do not know you.

BROMIDE.—Will you be kind enough to let me know, in your next issue, the best method by which I can turn a black and white bromide print into a sepia colour print?—S. JACKSON.

Bleach in:—

A. Ammonium bromide .....	300 grs.
Potass ferricyanide .....	300 grs.
Water .....	20 ozs.
Wash and immerse in:—	
B. Sodium sulphide .....	100 grs.
Water .....	20 ozs.

LANTERN.—As we have not used the apparatus we cannot answer your questions with any authority, but we believe the bricks are not peroxide only. We should advise you to consult a lantern expert, such as R. R. Beard, 10, Trafalgar Road, Peckham, S.E., who could probably adapt the apparatus to your wants.

STAINS ON NEGATIVES.—In fixing a plate a part was not covered with hypo during a portion of the time, and is stained dark brown. Can it be removed? Another plate is stained in patches, caused, I believe, through damp or liquid being in contact with it before exposure. Is it possible to remove this?—CARELESS.

In both cases try the method of removing silver stains on page 965 of the "Almanac"—viz., soaking the negative in: Potass iodide, 200 grs.; water, 10 ozs.; and after washing transferring to: Potass cyanide, 300 grs.; water, 10 ozs.; in which rub the negative with a pledget of cotton wool. If the stain does not yield to this treatment try a solution of iodine (in potass iodide), instead of potass iodide alone.

DEPTH OF FOCUS.—I have a 5 inch lens, working at  $f/6.3$ , and I want to know the depth of focus when an object 50ft. away is sharply focussed. The depth constant of the lens is  $3 \times 3 = 9$ ;  $9 \times 100 = 900$  inches = 75 feet. The hyperfocal distance of a 5in. lens working at  $f/6.3 = 75 \div 6.3 = 11.904$ ft. = 142.848 inches, 30 feet = 360 inches. The nearest point is therefore  $(142.848 \times 360) \div (142.848 + 360) = 51425.280 \div 522.848 = 97.557$  inches = 8 feet 2.357 inches. The farthest point is therefore  $(142.848 \times 360) \div (142.848 - 360) = 51425.280 \div (-?) = ?$ —Toxo.

From about 8ft. 6in. up to infinity. You are focussing on a point beyond the hyperfocal distance, hence the far limit of depth must be infinite. You need not work out such problems

to these places of decimals, because the results are only approximate. Nothing is gained by considering the decimals of an inch, especially when they are wrong, as yours are. If your lens is an anastigmat the depth is probably less than that given by the formulæ.

**ARTISTIC LENSES.**—Can you give me the name of a firm of English agents who supply the artistic lenses, including the adjustable landscape lens described in some recent issues of the Journal?—**DIFFUSE.**

The Hermagis "artistic" lenses are stocked by Mr. F. C. Clarkson, Colchester. We are not aware of an agent here of the "adjustable landscape lens," but we think Messrs. A. E. Staley and Co., 19, Thavies Inn, E.C., supply something of the kind.

**BOOKS.**—I shall be obliged if you can advise me on the following points:—(1) A book on photographic chemistry, suitable for a student. (2) A good book on colour photography, not the two, three, or four-colour printing processes.—**E. N.**

(1) "Chemistry for Photographers," by C. F. Townsend (Dawbarn and Ward. 1s.). (2) No such book. You had better get "Natural Colour Photography," by E. J. Wall (Dawbarn and Ward. 2s.).

**A. Z.**—In our next.

**WEAK BROMIDES.**—In doing an enlargement (bromide) one is apt to get a weak print. Would intensification with mercury and ammonia have any detrimental effect on its colour or permanency, or can you suggest another intensifier?—**SUSSEX.**

We cannot recommend the process on the ground of permanency. It is the least permanent of intensification processes, with the exception perhaps of uranium. A better intensifier would be mercury, followed by sulphite; or if that does not give sufficient intensity, mercury, followed by a non-staining developer, such as hydroquinone, made up with plenty of sulphite. Both will alter the colour.

**LANTERN MICROSCOPE.**—I have a Leach Chadwick lantern microscope, with a lin. objective, and two magnifiers, A and B. I have my ordinary lantern, worked with a 3-burner acetylene jet. Information as to the best way to use the microscope and the best light gratefully received. I wish to take it about in villages, etc., etc., so require a very practical way of showing microscopic slides. I presume it will be better to have another lantern adapted for the microscope, instead of altering my present one. Please name the best book on lantern microscopic work.—**CHARLES E. S. BELOC.**

If your lantern is of solid and substantial build we think it would be possible to have a separate stage fitted to it to carry the lantern microscope, but if it is of the cheap variety it will be useless for this purpose through lack of rigidity. If you are contemplating projection to a fair size, say 12 feet, you will require limelight, and we should advise you to use the mixed jet, or one of the ether saturators. There is no book we know of especially on lantern microscopic work, but we believe it is touched upon in "Optical Projection," by Lewis Wright.

**STAINED FINGERS.**—One of our people is very much troubled with stained finger-nails, and never so much as since we have used metol. Can you give any advice other than finger-stalls (which are a nuisance), to avoid the trouble, or at least minimise it? Sometimes the nails are literally mahogany colour for weeks. In course of work he handles gold sulphocyanide toning, pyro ammonia developer, metol, carbonate, bromide developer, platinotype developer, and, of course, hypo. It seems to me it is using the various chemicals in succession, and the consequent deposit of one on the other, which causes the trouble. After gold toning he fixes his hands in hypo. Could you tell us which chemical is the principal cause of staining, and whether, if chemicals were used in a different order, it would be lessened? The quicks of the finger-nails are very much broken, sometimes raw, from using metol. That, I suppose, is unavoidable, except by using finger-stalls. Would using the stalls for one process lessen the difficulty? It appears to me to be a chemical question.—**A. CONSTANT READER.**

The use of metol for a long time will render the user liable

to worse than stains—namely, swelling and inflammation of the fingers. The only remedy is usually to stop the use of this substance; but a palliative measure is to rub lanoline freely into the hands after work is finished. Of course, metol and other developers will stain to a much greater extent if the hands are afterwards immersed in iron solution, such as platinum developer. We think if your operator made a point of keeping his fingers covered with stalls when doing platinum work the staining would largely disappear. The question is a personal one, depending upon the peculiar character of the worker's hands.

**SEPIA UMBRELLA HANDLES.**—Some time ago I asked for a process to colour mother-of-pearl. A customer of mine has some mother-of-pearl handles for umbrellas, which he wished to colour sepia. I have coloured some for him in steel colour, which I did as follows:—I dissolved one ounce of nitrate of silver in 80 per cent. ammonia, about one pint, put the handles in an airtight jug for about twenty-four hours; then I exposed this to light, which becomes a nice steel colour. Is it possible that I can turn this steel colour into a sepia, after or before it is exposed?—**H. P.**

We would submit to you that this is scarcely a photographic question. We can only advise you to try soaking the articles in a solution of sulphide of soda, which possibly may have the desired effect.

**ARTIFICIAL LIGHT FOR PORTRAITURE.**—(1) Can portrait work be done in a studio, three-quarter length and bust, cabinet size, by incandescent gaslight? If so, how many lights (ordinary mantles, about) would be required? Portrait lens  $f/4$  to  $f/6$ ; S.R. plates; exposure, three seconds, about. (2) Can retouching be done as well by gaslight reflected as by daylight? (3) Could I do enlarging without a condenser, with three or four burners, incandescent, in a row with a reflector behind and opal or ground glass in front, to diffuse the light, sizes from 1-1 plate down? (4) Where can I obtain a piece of glass surface, silvered, for a reflector camera? (5) What will prevent mildew on camera bellows?—**H. M.**

(1) Yes, certainly it can. The greater the number of lights the shorter, of course, will be the exposure. You had better have special mantles, as you would require a goodly number of the ordinary ones, unless you are prepared to give long exposures. We should recommend you to get a prospectus of Adamson's gaslight arrangement for portraiture, Messrs. Still and Co., 22, Charles Street, Hatton Garden, E.C., or of The Tress Company's light, 42, Oxford Street, W.C. (2) Yes; but it is more trying to the eyes. (3) Yes; but the exposure will have to be much longer than with a condenser. We should advise you to use a condenser. Except for the larger sizes, they are not expensive. (4) Messrs. Penrose and Co., Farringdon Road. (5) Nothing but keeping the apparatus in a dry place.

THE death took place at Barrow last week of Mr. W. Stewart, photographer, of Dalton Road.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

An exhibition of American professional photographs opens at THE BRITISH JOURNAL OF PHOTOGRAPHY on Monday next, at 10.30. (P. 27.)

Tests of flaming arc lamps for portraiture on orthochromatic plates have shown that there is little advantage over the use of enclosed arcs and ordinary plates. (P. 19.)

A formula for the thiocarbamide toning bath has been given by M. Crenier, and should be used with the proportions mentioned in the article on Page 22.

A series of notes on the correct mounting of stereoscopic prints deals with this question as regards separation, trimming, and the colour of the mounts. (P. 18.)

Edinburgh has been named as the Convention meeting-place for 1908. (P. 34.)

The death is announced of Mr. S. D. McKellen, originator of the modern type of camera. (P. 28.)

An actress in Berlin has been unable to recover damages for a highly reprehensible use of her photograph. (P. 17.)

A clever skit by an American cartoonist on modern art portraiture in photography is reproduced on page 22.

At the Royal Photographic Society, on Tuesday, an exhaustive paper was read by Dr. Mees on the destruction of the latent image and the action of desensitisers on plates. (P. 33.)

Mr. F. Benedict Herzog, according to "Camera Work," builds up the figure studies admired at the last Salon from bromide prints of single figures cut out with a pair of scissors. (P. 28.)

A developing machine for roll film and a viewing instrument for panoramic pictures are among the patents of the week. (P. 30.)

## EX CATHEDRA.

### American Professional Photography.

On Monday next at our offices an exhibition of portraits by leading professional photographers in the United States will be opened, and may be inspected daily, at the times which will be found advertised in another page, until February 23. We have to thank our good friend, Herr R. Duhrkoop, of Hamburg, for the opportunity of showing these photographs to our readers. The collection of prints, with others for which we have not space, was sent to Herr Duhrkoop, and has been shown by him during the last month or two at his studios in Berlin and Hamburg. The photographs include examples of the work of men who are almost as well known by name on these shores as in the land of their residence. To name a few, Pirie Macdonald, E. B. Core, and W. N. Hollinger, all in the front rank of New York photographers, are represented by a number of examples each. Garo, of Baltimore, one of the best men in feminine portraiture, has a style which is always unmistakable. F. W. Porter is another whose refined work is quite foreign to British ideas of American taste, and, lastly, the largest number of portraits are by J. S. Strauss, of St. Louis, probably as successful a photographer on original lines as any living. One of Mr. Strauss's photographs is a study of Herr Duhrkoop as the Pope, and is reproduced in the catalogue of the exhibition, which will be presented to each visitor. We publish on another page a few notes of the men whose work British photographers may now see on the wall of the "little gallery" at the BRITISH JOURNAL OF PHOTOGRAPHY'S offices.

### A German Actress and her Photographs.

A worse state of things as regards the rights of an individual to his or her face appears to prevail in the realms of the autocratic Kaiser than in America even. The case is reported of an actress—Miss Westergaard, of the Metropol Theatre, Berlin, whose portrait in costume was taken not long ago by a firm of photographers. The latter retained the copyright in the photograph and circulated the actress's portrait as a postcard, which, presumably, bore her name. The negative, however, came into the hands of a firm in Vienna, and soon afterwards transpired the incident which has given rise to an action in the law courts. A journal of a certain character published an illustration representing a young girl stretched upon a divan in extremely scanty attire and represented as saying: "I don't care much for oil paintings, but an engraving in the form of a bank-note is very much to my taste." The subject of the photograph was Miss Westergaard, and the face in the reproduction had been extracted from the portrait taken of her in Berlin. Yet the paper which published this libellous photograph obtained an acquittal on the ground that it had no knowledge of the

identity of the subject of the photograph. It is a good thing for it that the incident did not occur in England. It will be remembered that not long ago Miss Marie Studholme obtained damages from a dentist who to advertise his business showed a photograph of the lady before and after the supposed addition of a set of artificial teeth.

\* \* \*

#### Winter Water Supply.

The alternations of frost and thaw which have been a characteristic of recent weather have not hitherto resulted in any serious inconvenience, for the reason that the frost—we speak of the South of England—has not been severe. Yet it is well to be prepared for contingencies as regards the damage which may result to water-pipes in a protracted frost under conditions of severity. All exposed pipes should receive protection. At most large ironmongers a special felt for the purpose is sold. Two or three thicknesses of this non-conducting material wound round the pipes will effectually prevent their freezing. Failing the felt, "hay-bands," which may be had at most cornchandlers, will answer the purpose. If the pipes are secured to a wall, so that the felt cannot be wound round them, it may be closely nailed over them. Another good way of preventing the water freezing in the pipes is to leave it constantly dribbling at all the taps. Should the service pipe from the street main be laid close to the surface of the ground, as it sometimes is, it should receive further protection by having more earth placed upon it, or, better still, by the ground being covered with six or eight inches of good stable manure. Thus protected, the supply pipe is scarcely likely to become frozen, even should the weather prove to be severe.

\* \* \*

#### Horizontorium Pictures.

We have several times drawn attention to the solid relief perceptible in a photograph when it is seen from its one proper view point or perspective centre, and in a recent leader we pointed out the importance of good "monocular relief" in the case of stereoscopic slides. A writer in the January number of "The Photographic Monthly" gives some striking illustrations of the monocular relief obtained under somewhat unusual conditions. His results were produced in a camera so arranged as to place the plate in a horizontal position. They therefore are similar to bird's-eye views taken from a near view-point, and if observed from a usual standpoint, show what many people would style violently distorted perspective. When viewed from the one proper point the perspective appears correct (as, of course, it is), and the subject stands out in strong relief. Being similar to the old hand-drawn puzzle pictures known as "Horizontoriums," the author of the article has adopted that name for his photographic results. The effect of relief in these pictures is aided by the unusual conditions, for when looking down on a subject that stands on a horizontal plane the varying distances of the different vertical planes is very obvious, much more so than when the same subjects are viewed from a lower standpoint. There is nothing in any way stereoscopic in the effect. It is simply the result of perspective conditions that are rather more strongly marked than is usual, and it affords an excellent object-lesson in the importance of good perspective. It should be pointed out that the horizontal position of the plate has really nothing to do with the effect. The result entirely depends on the position of the lens relative to the subject, and the plate may occupy any convenient position. In the original "horizontorium" a horizontal position was selected for the picture plane to add to the apparent distortion, and so give to the result more of the character of a curious puzzle. So far as the relief effect is concerned this complication is altogether unnecessary, but still the apparent distortion has advan-

tages. The absurdity of the effect compels one to search for the correct view-point, while in the absence of any very obvious distortion the spectator is too apt to be content with a quite wrong point of view.

#### MOUNTING STEREOSCOPIC PRINTS.

In mounting stereoscopic prints there are three important matters for consideration; first, the amount of separation required; second, the trimming of the prints; third, the tone of the mount. All three of these matters are commonly dealt with in a haphazard fashion, but the effect obtained depends very greatly upon them, and many slides are marred by the obvious neglect of the very simple rules that should be observed.

The question of separation we have already dealt with partially in an "Ex Cathedra" note, in which we gave the rule that the print separation should be equal to the separation of the eyes *plus* the separation of the lenses and *minus* the separation measured on the negatives. The separation on the prints is, of course, measured between two corresponding points, and that of the negatives between the same two points; and the rule assumes that the negatives are taken on one plate in the usual type of camera, fitted either with two lenses or with a single lens that can be traversed from side to side so as to expose each half of the plate in turn. It is also assumed that the stereoscope is non-prismatic; if, however, prisms are used, the print separation should be increased by, theoretically, the width of one prism. In practice the prisms are seldom properly centred, and it is advisable to allow rather less than the full width.

Stereoscopic negatives are, however, often produced in less conventional ways, and the rule then requires modification. The first and most important of these varying methods is the use of a single camera that is bodily moved sideways between the exposures, this being equivalent to the use of two separate cameras placed a certain distance apart. The lens separation may then be very great, and, as we have before pointed out, a correct mounting separation is of the greatest importance when the views have been secured from widely different points of view. The rule is a very simple one to apply, and the distance between the two view points need not be measured, as everything is recorded on the negatives. Place the two negatives side by side with edges touching, and in the same relative positions that they occupied during exposure. Next measure the separation of two corresponding points on the negatives and also the width of one of the plates, which should both be of the same size. The proper mounting separation is then equal to the separation of the eyes *minus* the separation measured on the negatives and *plus* the width of one plate.

The only other case worth consideration is that in which the camera is moved as before, but the two negatives are secured on one plate, their relative positions being changed by the use of a repeating back. It is very often assumed that in such a case you can print direct from the negative on to one piece of printing paper, and so secure two positives that need no cutting. As a matter of fact, cutting is necessary, for the positives thus obtained are at the wrong separation, hence the various expedients for producing negatives in correct relative positions are of little or no advantage. The correct mounting separation is arrived at as follows:—Measure the separation of two corresponding points on the negatives, and also the amount of movement of the repeating back relative to any fixed point on the camera. This latter measurement can always be taken from the camera itself if the back is moved to its extreme limits, but if the possible movement is unlimited the measurement must be noted at the time of exposure. The

print separation is then equal to the eye separation *plus* the negative separation *minus* the movement of the back. In this case, again, the lens separation need not be noted. If the particular object points that we measure between are at an infinite distance the print separation is, under all these rules, equal to the eye separation. But if no infinitely distant objects are included this simple modified rule cannot be applied, and the nearer the objects and the wider the separation of the lenses the more important does it become to observe the correct rule, for non-observance may give most obvious distortion.

The next point for consideration is the trimming of the prints, and it is best to conduct this process by rule also, otherwise most unpleasant results may be produced. According as the prints are trimmed so the objects in the picture appear in the stereoscope to be behind the mount, on the same plane with it, or in front of it. As a general rule the first effect is the one to aim at, and it is very simply attained by the following method of trimming. First, trim the two prints as nearly alike as possible. It is impossible to cut the vertical margins so as to show precisely the same amount of detail at the corresponding edges, but one can get very near to correspondence. Then lay the prints side by side with margins just touching, and measure the distance between the images of the nearest point represented. This dimension fixes the extreme limit of width of each print, and they must be trimmed down at the outside margins only, until the width is just a small fraction of an inch less than the measured distance. If the nearest object is at the margins the strip taken off need not exceed one-fifteenth of an inch, and in many cases it is unnecessary to take off this small amount. On the other hand, if the nearest object is in the centre of the view it may be necessary to take a quarter of an inch, or even more, off the edges. It has often been stated that from one-sixteenth to one-eighth of an inch is the right amount to remove from the outer margins, but any such hard and fast rule is incorrect. The trimming must vary with the subject.

The correct trimming rule depends on the law of convergency that governs all stereoscopic effect. The nearer an object is the less is the separation of its two images. Hence if the subject is to appear as though viewed through an opening in the mount the corresponding margins of the prints must be nearer together than the images of the nearest object. If the rule is not observed, some parts of the subject will appear to be in front of the mount, and

great confusion may exist at the horizontal margins. If only distant objects are at the margins the prints will differ greatly in the amount of subject they include, and as objects shown in one print alone are not seen stereoscopically and often cause confusion, it is desirable to avoid such dissimilarity. This can only be done by selecting the subject and point of view in such a way as to ensure fairly near objects being at the margins.

If it is desired to bring the objects in front of the mount the procedure is very similar, but the width of the prints must be slightly *greater* than the separation between *distant* points, and the extra trimming must be carried out at the *inside* edges of the prints. Such a mode of trimming is seldom justifiable and a far better method is to cut the negative, re-arrange the two halves with proper print separation, vignette both halves, and print together on one piece of paper. No margins then appear, and with some subjects the absence of margins is most advantageous.

The third matter for consideration is the tone of the mount, and though this should be governed by a very simple and obvious rule, no rule whatever seems to be generally observed. The mount must always either fulfil the purpose of a perforated screen through which the object is observed, or of a background against which it is seen; and in either case the tone of the mount should be in conformity with the lighting of the subject. If the object is front lighted, that is, if the direction of the light is from the observer to the object, then obviously the screen or background should appear to be illuminated from the same direction, and should be light in tone. If the screen effect is produced and the subject is obviously lighted from some direction behind the screen, then, as the latter if it actually existed would be in shade or comparative darkness, the mount ought to be dark. A perfectly black mount is very suitable for a brilliantly lighted street scene, because the effect produced is very much that of a view through the window of a room which is dark by comparison with the outside. With an interior view a black mount is frequently objectionable because the idea of looking into a building through an aperture in the wall of a quite dark room outside is more or less offensive to the reason. A light mount gives a more reasonable effect, but a neutral tint that gives less defined margins is generally best. There is much to be said for the vignette effect in cases where the effect of viewing the subject through a screen is not quite in conformity with a natural state of things.

## THE USE OF FLAMING SUNLIGHT ARCS IN PORTRAITURE.

In our issue of March 31 of last year, in an article entitled "A New Artificial Light Studio," attention was drawn to the use of flaming sunlight arcs for photographic purposes, and in the succeeding issue a letter from Mr. Arthur Payne was printed, suggesting that for portrait work such lamps might be found less expensive in consumption of current, and valuable as helping to obtain better colour rendering. We have had a number of experiments made, not with the "Excello" arc lamp mentioned by our correspondent, but with cored carbons of a similar kind to those used in the "Excello" lamp, but employed in an ordinary enclosed arc lamp.

Three points were considered—viz., the question of cost of running the lamp; the relative rapidity of exposure obtained with the sunlight arc and a highly colour-sensitive plate as against an ordinary violet arc and a rapid non-iso plate; and the improvement in colour rendering of draperies and flesh.

From the photographer's point of view, the question of cost of running an electric light installation is an important one. Mr. Payne, in his letter referred to, says, giving the actual cost at Newcastle-on-Tyne, "as each lamp is said to be of 1,600 candle-power, the total cost for a light of 6,400 candle-power is 4d. per hour. The illuminating power of ordinary arc lamps consuming the same quantity of current is said to be 475 candle-power." These figures are evidently given from a maker's list or circular, and are quoted by our correspondent guardedly. The matter is a rather deep one, and as yet no very satisfactory relationship has been established between actinic power and consumption of electric energy. What is meant by 6,400 candle-power and 475 candle-power? Are these figures given in relation to photographic illumination, or are they intended to indicate the efficiency of the particular type of lamp for street illumination? It is known to everyone who has observed the various street

illuminants that the penetrating power of the ordinary arc in foggy weather is much less than that of a yellower but more feeble light. Under what conditions were the measurements taken which formed the basis of the above figures? In the "Excello" lamps the carbons are placed inclined towards each

other like the two sides of a letter V, and by means of an electro magnet the arc is repelled downwards so that the maximum illumination is downwards, which is exactly what is required for street illumination. If the comparison as quoted above were made against an open arc lamp with short arc, and the measurement taken from beneath the lamp, such figures might be

obtained, but they would be utterly misleading if unqualified and made the basis of a comparison between, let us say, ordinary enclosed arc lamps and flaming sunlight arcs for portrait work. In fact, the statement that a lamp gives a certain "candle-power" is always extremely vague.

In the experiments we have had made a large lamp of the enclosed type was employed, exposures being made with solid carbons first, and then further exposures with the cored carbons

giving the sunlight arc. The amount of resistance put in was not varied, and the measurements of electric energy were as follows:—Ordinary enclosed arc: 102 volts, 25 ampères, approximately  $2\frac{1}{2}$  units per hour. At power rate of 2d. = 5d. per hour. Sunlight arc: 101 volts, 24.5 ampères—i.e., practically equal to ordinary arc. These are the units per hour actually consumed in the lamp, the volts given being volts across the lamp. The object of so taking the measurements was to determine whether the cored carbons took more or less electric energy. The sunlight arc was undoubtedly longer than the ordinary arc, but as equivalent exposures on the different plates were ascertained by trials the relative photographic value was thus arrived at. The units per hour registered by the meter would, of course, be different. As the lamp was running on a 240 volt circuit, the units the meter would register would be 6, the lamp taking  $2\frac{1}{2}$ , and the remaining  $3\frac{1}{2}$  being lost in the resistance. When lamps are run in series the resistance loss is a smaller one, one lamp serving as a resistance for the next. This, however, applies to lamps of practically any type, and whether using cored or solid carbons.

At this point it may be well to mention a matter of great importance, the comfort of the sitter, which is often quite overlooked by the theorist. A yellow light is always far more glaring to the eyes than one of a bluer character but rich in violet rays, and the heat rays which are present to a greater extent make the light trying.

We may now turn to the results obtained during the experiments, and consider them from the colour rendering and relative exposure point of view. Our blocks are the same size as the bromide prints from which they were made, these being enlarged about four diameters from the original, absolutely untouched cabinet negatives. The half-tone screen will no doubt tend to subdue the freckles, but it is anticipated that by reproduction on such a large scale the flesh rendering may be apparent.

Z is from an exposure on an Ilford "Zenith" plate, using stop f/11 and an exposure of half a second with the ordinary solid carbons. The plate was developed in the ordinary way, by time, with a no-bromide pyro soda developer.

P is on a Wratten and Wainwright Pinachrome bathed plate, the carbons being changed to cored carbons and the exposure being one second at the same lens aperture. The distances from sitter to light and sitter to lens were identical, none of the appliances being moved. It may be well to state that the

requisite exposures were ascertained by experiment, strip exposures being first given in the case of both Z and P. P was developed with the same strength developer to a proper degree of density. The two negatives, as such, are quite indistinguishable, and it is necessary to look for identifying marks in order to ascertain which is which.

So far, then, as flesh rendering is concerned from the point of view of retouching the portrait negative, the idea that the use of a sunlight arc will diminish to any appreciable extent the retoucher's work is shown to be untenable.

Where coloured draperies and light yellow hair occur, however, the colour rendering of these is greatly improved, and if they form important elements in the composition the gain is very considerable.

D

Spectrum of Sunlight Arc with and without light filter, on Wratten Pinachrome Backed Plate.

A further experiment was next made, carrying the correction still further, indeed, actually over-correcting to a slight extent. In order to give a filter of definite strength a liquid filter was employed, a 5 per cent. solution of potassium chromate in a Zeiss cell of a quarter of an inch inside measurement. Again a series of trials was necessary to determine the multiplying factor of this filter with the pinachrome bathed plate in the yellow light employed. Such multiplying factor proved to be from 6 to 8, the filter cutting out practically the whole of the blue and violet rays. PF is from the photograph taken on the pinachrome plate exposed through this filter, the exposure being 6 seconds at  $f/11$ —that is, giving the same exposure as for P, but multiplied by 6 for the light filter. The improvement in flesh rendering is now very marked, and from this point of view it may be safely said that no retouching of freckles is needed. A

great improvement is also noticeable in the expression of the eyes, which lose the objectionable glittering effect.

Halation, however, became troublesome, especially if the exposures were at all full, and a backed plate should certainly be used, backed, of course, by the makers, for these bathed plates are so sensitive that they should be handled, if possible, in complete darkness. At the most the merest trace of deepest ruby light is all that can be employed, just sufficient to see the whereabouts of the graduate and the edge of the developing dish. The pinachrome plates worked beautifully clean with the no-bromide pyro soda developer, and, as some were developed after they had been kept for seven weeks, there need be no fear of deterioration after careful storing for a reasonable length of time.

To summarise, it appears that an improvement in colour rendering of draperies, etc., may be obtained with the sunlight arc, using a colour-sensitive plate of the type employed in the

Spectrum of Ordinary Arc on "Zenith" Plate.

experiments, the exposure being about double that necessary when working with a rapid ordinary plate and the ordinary arc. By the use of a light filter of the character indicated a marked improvement of draperies and flesh rendering, with an almost entire absence of freckles, is obtained. This exposure of 6 seconds at  $f/11$  becomes only  $1\frac{1}{2}$  seconds at the quite usual aperture of  $f/6$ , and this certainly must be regarded as a very rapid exposure for approximately colour-corrected results. The results, as far as colour rendering goes, confirm those obtained by Mr. Howard Farmer some years ago, and communicated by him to the Royal Photographic Society (vide "Phot. Journal," 1902), though his experiments, we believe, were made with the Adamson super-incandescent lamp.

The remaining blocks illustrate the spectrum of the sunlight arc photographed on the pinachrome plate with and without the filter, with varying times of exposure, and also the spectrum of the ordinary arc on the "Zenith" plate.

THE exhibition of the Leicester and Leicestershire Photographic Society will be held from March 7 to 16 inclusive; entries close February 16. Arrangements have been made whereby exhibitors at the Sheffield and Nottingham exhibitions can, if desired, have their exhibits forwarded to Leicester free of charge. Entry forms and full particulars may be obtained from the exhibition secretary, Mr. Lewis Ough, "Fernleigh," St. James's Road, Leicester.

It will doubtless be of interest to many secretaries to learn that Messrs. A. E. Staley and Co. have a small collection of lantern slides illustrating their 8-lens system Planastigmat lenses, which they will be pleased to lend to any photographic society who would like to exhibit them. Applications for loan, or further particulars, should be addressed to the above firm, at 19, Thavies Inn, Holborn Circus, London, E.C.

## "PROGRESS" IN PHOTOGRAPHIC PORTRAITURE.

WE are glad to see Mr. Steiglitz in the current issue of *Camera Work*, making fun of the craze for "wuzziness," which has been a common feature of elementary attempts at pictorial photo-

graphy. The two cartoons reproduced herewith on a smaller scale than the originals, give the impressions of the clever American caricaturist, Mr. J. Montgomery Flagg, of the newest photo-

graphy compared with the old. It is no exaggeration to say that the later photograph of the gentlemen with the side whiskers is no worse than some of the things which are shown under the blessed banner of "pictorial photography." Mr. Steiglitz, whose own work has always been very photographic, has made a stand by example and precept, for the preservation in works of photographic art of the qualities which are most admirably photographic.

In this respect Mr. Steiglitz stands in the opposite camp to M. Demachy, whose pictorial tenets are quite latitudinarian in the licence they grant him of making photography subservient in the final product of his art. Yet both Mr. Steiglitz and the leader of photography in France have discouraged the extremes of diffused definition, which in the past more than recently have made photographers a laughing-stock in the eyes both of artists and the public. A little good-humoured caricature such as Mr. Flagg's should help to turn the efforts of the immature pictorial workers in other directions.

## THE THIOCARBAMIDE TONING BATH FOR P.O.P.

QUERIES which occasionally appear in the "Answers" column show that the toning bath for P.O.P. in which the substance thiocarbamide replaces the usual sulphocyanide is sometimes employed, but we imagine that its use is very limited and occasional. The reason is no doubt the chemical peculiarity of thiocarbamide through which prints which have been satisfactorily toned may be easily spoiled in the after operations. This peculiarity is the ability of very weak alkali, such as many ordinary tap waters, to decompose the silver compounds of thiocarbamide which exist in a print which has been toned with the aid of thiocarbamide but not fixed. These compounds are removed by a strong hypo bath, say the usual ten per cent. employed for P.O.P.; but they will be decomposed with very objectionable results if they are allowed access to ordinary tap water. In practice this means the very simple rule that prints must be transferred direct to the fixing bath from the thio-

carbamide toning solution, but as thiocarbamide has to be acid, and as the fixing solution must not be allowed to accumulate doses of acid, or it will give rise to stains and fading equally fatal to the print, it must be strengthened against their entrance by the addition of some alkali—best, carbonate of soda, about  $\frac{1}{4}$  oz. in a pint bath of hypo containing 2 oz. of hypo. These facts, which are the source, we believe, of most of the failure with thiocarbamide as a toning agent, may be emphasised in quoting an enconium of the thiocarbamide bath which appears in a recent issue of the *Photo-Gazette*, by M. V. Crenier. M. Crenier would have us believe that the thiocarbamide bath is the only one which cannot fail its user at critical moments, and though we would be unwilling to make such a claim for a solution which depends for its reliability on the manipulation which it receives, yet we would draw attention to the bath as one which may solve the difficulties of those who complain of double tones,

and of being unable to get rid of them by the sulphite modification of the sulphocyanide bath, a variation of the usual sulphocyanide formula which in many cases will be found sufficient to prevent the recurrence of the trouble.

M. Crenier says:—

"After numerous experiments with other methods of toning I have adopted the thiocarbamide bath as presenting the most advantages as follows:—It is very easy to make; it can be used immediately when made; it never gives double toning, and all tones from red to blue-black can be obtained with it; it tones very quickly, at 60 deg. Fahr. a violet tone can be obtained in five minutes; it remains active for a long time; it is not necessary to overprint so much, as it reduces the prints but little.

"The method adopted for making it is the same as suggested by Valenta:—

Gold chloride .....	2½ grs.	.25 gms.
Distilled water .....	½ oz.	25 ccs.
Add, to dissolve precipitate first formed, sufficient of:—		
Thiocarbamide .....	10 grs.	1 gm.
Distilled water .....	2 ozs.	50 ccs.
About 144 minims (14-15 ccs.) will be needed. First add		
Citric acid .....	48 grs.	.5 gm.
and		
Distilled water to .....	10 ozs.	500 ccs.
and finally		
Salt .....	96 grs.	10 gms.

"The prints should be printed slightly darker than they should

be when finished; they should then be washed in several waters and then immersed in the toning bath and kept on the move. After toning the prints must be well washed and then fixed in a hypo bath, with the addition of bisulphite, if the fixing bath is to be used over again. On drying, the prints become slightly colder."

"In summer it is advisable to add a little alum to the bath, and in winter the bath should be warmed to 60 deg. Fahr. With some papers it is also advisable to dilute the bath with an equal quantity of water, or else it tones too quickly. The usual quantity the bath requires is 170 minims for thirty-five square inches of prints.

"The tones obtained are remarkable for their freshness and variety. Some papers with a pink-tinted face do not give such good results as those with mauve.

"Some operators object that it takes longer to finish the prints with the separate baths; but this does not apply to this bath, as it certainly requires from twelve to fifteen minutes in the combined bath to obtain perfect fixation. In the thiocarbamide bath it only takes about five minutes for toning and ten for fixation in a 10 to 15 per cent. solution of hypo.

"If it is necessary to save time, two prints can be toned at once by placing them back to back, and occasionally separating them. If two prints from the same negative are toned, one with the combined, and one with the thiocarbamide bath, the results will be very convincing. Very frequently paper which has been in stock for some time, and tones badly in a combined bath, will tone well by this method."

## AMERICAN PROFESSIONAL PHOTOGRAPHY IN LONDON.

At the present time Messrs. J. H. Dallmeyer, of 25, Newman Street, Oxford Street, London, W., are exhibiting in their show-rooms a small but choice collection of portraits by American professional photographers made without exception with Dallmeyer lenses. With the exception of those taken with the Dallmeyer-Bergheim lens, of which there are one or two examples, the negatives are usually done with the 3A and 4A portrait lenses; and one thing which the visitor should notice before he looks at anything else, is the good use which is made in several cases of the large 4A lens for work which is little larger than cabinet. We referred to this very fact only a week or two ago in an article on studio lenses, and those who noted the advice at the time may now go and see what it means in practice. They should notice particularly the portraits by Mock, Hayes, and Schreiber in this connection. The portrait by Pirie Macdonald of Mr. Carnegie, we believe, is a piece of 4A work. An identical print is among the collection which will be shown at our offices. Of other exhibitors whose work Messrs. Dallmeyer have brought forward are Dudley Hoyt, Rochester; S. R. Lewis, Utica, N.Y.; Notman, Montreal, whose portrait with the Bergheim lens is worthy of special notice; and F. J. Feldman, El Pasco, Texas. The collection can be seen daily until 4 o'clock and on Saturdays until 1 o'clock.

The exhibition of American professional portraits which we shall bring before our readers on Monday next is made of work by a quite different set of photographers. Only in two instances, those of Core and Macdonald, are there exhibitors common to the two collections. Some fifteen photographs are the work of Mr. J. S. Strauss, of St. Louis, the man who has made his studio as famous as any institution in his city. This result he has achieved purely by his original methods of business. At one time he formed a collection of portraits of all the eligible bachelors of St. Louis, which was on view to any caller in the gallery, furnished, as are all the apartments in his establishment,

in as substantial and tasteful style as money can buy. Music is provided to complete the pleasure of the visitor to the Strauss galleries, and ladies out shopping in St. Louis will think of calling in at the Strauss house as naturally as the London lady of fashion visits the Dowdeswell. Mr. Strauss recently held an exhibition of portraits of personages in English society by Mr. Walter Barnett.

Mr. Pirie Macdonald's latest impression of himself.

Mr. E. B. Core, of New York, is a quiet, pleasant man free from the characteristics of many Americans. He photographs only children, or will photograph a grown up person only with a child. On one occasion the two aged heads of a family of multi-millionaires, grandfather and grandmother, and with enough money to buy half the State of New York, arrived in Mr. Core's studio and asked to be photographed. The order was politely refused, by informing them that he could consent to take their

photographs only if they brought one of their children's children with them and allowed a group to be made of the three.

Mr. W. N. Hollinger commenced life as a tintype tout on a seaside beach. He is now in the very front rank of New York photographers. He is the man who has made a success of the one-print business. He will perhaps take half a dozen negatives of a sitter, but will supply only one print, the size, style, and mounting of which—everything except the price—is left absolutely to his discretion by the sitter.

Mr. Pirie Macdonald is a "photographer of men," but advertises his business to women on the shrewd policy that men are driven to a photographer's, as they are driven to drink, by their women folk. Mr. Macdonald understands pictorial advertising. One of his designs shows him in the act of ejecting from his studio the perfectly-dressed effeminate dude of the musical stage type. Over the fanlight are the words "PHOTOGRAPHER OF MEN." The fancy portrait of Mr. Macdonald which we reproduce is taken from his New Year's card addressed to the B.J.

## THE COMPARATOR: A NEW PHOTOGRAPHIC PHOTOMETER.

(A Paper Read before the French Photographic Society.)

To estimate the relative intensities of two sources of light from a photographic point of view, the following method may be employed: To receive them on two identical sensitive surfaces and to vary their action till equal effects are obtained, and to note the exposures necessary to give this equality. From the ratio of the latter the ratio of the corresponding actinic intensities can be deduced.

If, for example, it is desired to determine the absorptive power of a certain medium, one sensitive surface should be illuminated by the direct light, and the other by the same light after it has passed through the absorptive medium.

The two exposures for each test being generally of unequal duration cannot be quite simultaneous. If the action of the light is continuous for each, it necessitates (in order that it may be exact) that the intensity of the light used should not undergo any variation during the test. It is thus impossible to use daylight, notwithstanding the fact that this is constantly used in photography.

This troublesome necessity may be overcome when the ratio of the intensities of the light to be compared remains fixed, as in the pre-

permits of this suppression if their apertures are given the necessary shape. They ought to be cut in such a manner as to give regularly graduated exposures to different parts of the sensitive surfaces. After development the two plates should be placed side by side and the position of zones of equal density observed; these positions will give the corresponding apertures of the discs—that is, those which produced the equal results. The desired ratio will thus be determined by a single test.

M. Bellieni has realised this in a practical and elegant manner by placing the revolving discs in the dark slides of two ordinary cameras. They are revolved by two electric motors.

At the back of the modified dark slides are two frames to take plates 6.5cm. by 9cm., which are pressed against metal frames which limit the surface acted upon. The shape of each aperture in the discs is with one side straight and the other curved in an analogous manner to Scheiner's sensitometer, as seen in Fig. 1, and so that the ratio of the duration of exposure of two points of the plate depends entirely on the differences of their distances from the axis of rotation. Two outlines of this kind having been made, the first giving a ratio of time of exposure equal to two for differences of distance from the axis equal to 10mm., and the second giving the same ratio for a difference of 25mm. It will then be easy to calculate the others.

Fig. 1.

ceding example. The constancy of the absolute intensity of each light is no longer indispensable if the continuous action of the light is replaced by a discontinuous and rapidly intermittent action, such as is obtained by the rotation of a perforated disc in front of the sensitive surfaces. During the same total duration of exposure, two discs with unequal apertures give different times of illumination. If under these conditions equal effects are obtained, the ratio of the apertures of the discs enables one to determine the ratios of the luminosities of the two sources of light.

This amounts, in fact, to replacing a test of comparatively long duration by a large number of tests of very short duration, the effects of which are totalled. The final result will be just as if the luminous intensity remains practically constant during the time of each elemental test—that is to say, during the intervals of time comprised by two successive illuminations of the sensitive surface. It is always possible to satisfy this condition by giving to the discs a sufficiently great rapidity, and in practice it is not necessary to have recourse to extreme rapidities.

There only remains to overcome a serious inconvenience of this method: the necessity of a series of estimations to obtain equality of effects on the two sensitive surfaces. The use of revolving discs

Fig. 2.

The distance of the disc from the sensitive plate is reduced as much as possible, and does not exceed 1.5mm. The exterior axis ends in a double pulley and an arrangement for counting the number of revolutions. The discs can be set in motion by two independent motors, or may be coupled up and then actuated by one motor.

After development of a plate exposed behind a rotating disc the sector will have a graduated tint, becoming lighter the further it is from the centre. To compare the results of a test, the two plates must be developed together, and then cut in two along the middle radius of the sector. A half of each plate is then placed side by side on white paper or against ground glass lighted from behind and then shifted one against the other till the tint on each coincides at their line of contact; the distance between the circular edges of the two sectors immediately tells one the ratio of the times of exposure which gave equal results. The distances are, in fact, proportional to the logarithms of the corresponding ratios, and a table can be prepared for each kind of disc.

In practice glass or paper is divided into millimetres to enable the distances to be read off at once. There is nothing to prevent other methods of comparison of the relative positions of equal zones of density on the two plates. For example, the two halves of the

plates may be compared with the tints in opposite directions and the line found at the point of contact where the opacities of the two plates are rendered equal.

The first purpose of the comparator was a study of the loss of light of two lenses, based on the comparison of the illumination given by two small holes, the lenses to be examined being placed behind each hole. For this special purpose two V supports were fitted which could be moved both vertically and horizontally; this enabled the lenses to be rapidly placed in the camera and the centres of the lenses to be easily adjusted at the height of the small holes.

The cameras were directed for this test to a sheet of white paper, carrying two parallel black lines; the distance of the images of these bands on each plate indicated the scale of reduction, which it was necessary to consider when calculating the ratio of the illuminations.

The small holes were pierced in small screens, and outside these were plates of metal pierced with holes of some millimetres diameter, which limited the field, thus preventing the light from being reflected by the lens and forming spots on the plates.

Besides this special use, the comparator can be employed for any photometric determination of the same spot, and also to a study of the action of light on sensitive surfaces. It was also proposed to commence this last application to see what approximation could be obtained and to see if it would be useful to apply corrections to the rough results.

The questions to be resolved are principally as follows: (1) Two equal quantities of light given by the same illuminant, do they give equal effects when one is given continuously and the other intermittently? If not, how does the effect vary with the conditions of intermittence? (2) Two equal quantities of light given continuously by two different sources, do they give equal results? If not, how does the result vary with the intensity of the illumination?

The study of these questions is not new; it has been especially answered by Dr. Eder in his "System der Sensitometrie," the answer being given partly by the author's own experiences and partly by reference to the results obtained by Schwarzschild. It may be interesting to examine how the indicated laws apply to the particular case of the comparator.

All the tests were made with Lumière "Blue Label" plates, the two plates of each test were cut from the same 13 by 18 plate, and developed exactly the same in the same developer; the discs carrying the two apertures were revolved about 600 times a minute.

A series of tests relating to the first question were made with a source of light, a paraffin lamp, practically constant, and placed at equal distance from the two plates. The duration of each test was not more than four minutes.

In the first preliminary test two plates were exposed for a period equal to ten seconds, the one continuously and the other behind a special disc, opened for a twentieth of its circumference, and thus exposed for 200 seconds. The tint was directly darker on the plate which received the continuous exposure.

In the following test different exposures were given to two plates

placed behind discs having a ratio of 0.2 for 10mm. The results obtained were as follows:—

Ratio of Exposures.	Distances Calculated in Millimetres.	Distances Observed.
1.5	6	5 to 6
2	10	9
3	16	14
4	20	17 to 18
6	26	24
8	30	26 to 27
16	40	36

This shows that an intermittent action diminishes the effect produced by a certain quantity of light the more, the smaller the ratio of time of illumination is to the whole. It may also be observed that the observed distance is almost always very near the product of that calculated by 0.9. This may be expressed by the following rule: If  $t$  and  $t^1$  are the exposures of two plates,  $r$  and  $r^1$  the ratios of the corresponding intermittent exposures, so that  $rt$  and  $r^1t^1$  are the real exposures, the effects produced will be the same, not as  $rt = r^1t^1$ , but as  $rt^{0.9} = r^1t^{1.0.9}$ . It would be rash to generalise a law based on such a small number of observations and so slightly varied, but one may consider it as sufficiently near under the conditions and the limits of these observations; it applies, moreover, fairly well to the results given by Eder as obtained under analogous conditions.

Another series of tests relating to the two combined questions were carried out by allowing two illuminants of known ratio to act on two plates for the same time through revolving discs, the ratio of illumination being determined by placing the plates at different distances from the same source of light, which was an incandescent electric lamp with rectilinear filaments placed in a box with black sides to obviate reflections from surrounding objects.

The results obtained were as follows:—

Ratio of Illumination.	Distances Calculated.	Distances Observed.
6.4	26.9	26 to 27
14.2	38.3	37 to 38

In another test the plates were exposed to daylight reflected from white paper, through two small holes of equal size, but with different extensions for the two cameras. The discs were fitted with apertures having a ratio of 2 for 25mm. of distance. The ratio of illumination calculated were 2.25, the distance calculated 29.2, and the observed distances were 31mm. With the first form of apertures these numbers should have been 11.7 and 12.2.

In this second series of tests it will be seen that the observed distances differ very little from the calculated distances; this is also in accord with the results obtained by Eder. If one admits with him that, according to Schwarzschild, the effect of an illumination of an intensity,  $i$ , during a time,  $t$ , depends solely upon the product  $itp$ , it is sufficient to put  $p=0.9$  to reconcile the two series of tests; this value is very close to those cited by Eder.

In every case it may be said that in the conditions under which the experiments were made a pierced disc revolving does not act exactly as though it diminished the time of exposure in the ratio corresponding to its aperture, but rather as though it diminished the luminous intensity in the same ratio. It is then sufficiently appropriate to photometric applications.

H. COUSIN.

## COLOUR - FILTERS FOR ASTRONOMICAL PHOTOGRAPHY WITH REFLECTING TELESCOPES.

From the *Astrophysical Journal*.

(Concluded.)

As all dyed filters generally dry with a slight shift in absorption towards the red, allowance must be made for this; therefore two other glasses are coated with slightly smaller amounts of solution, and then dried rapidly by fan. Exposure to the spectrum are then made through each and any other further correction noted.

In coating the optical glass for the finished filter the drying cabinet (which should be large and roomy) is carefully dusted with a damp cloth, and the supporting plate carefully levelled. The glass being coated with the determined amount, and laid upon the levelled plate, the door is closed, and left so until dry.

In filters of exact adjustment, where there are two components, it will be found advisable to flow each plate separately, as a much closer result can be thus arrived at than by combining the dyes and flowing once.

The solution actually used for coating the glass plates was made up as follows:

Gelatine, 5.0 grams { Stock.  
Water, 200.0 cc.  
Dye solution A: Stock gelatine solution, 100.0 cc.  
Tartrazine, 0.15 gram.  
Dye solution B: Stock gelatine solution, 100.0 cc.  
Auriculin, 0.2 gram.

Of solution A 2.5 cc. was flowed upon the glass plate of 58 sq. cm. area, while 3.6 cc. of solution B was flowed upon the cover-plate of similar size. The actual amounts of dye on each surface would then be A=0.00375 gram, B=0.0072 gram.

This process seems lengthy in the repetition, but is in reality quite rapid in performance. Especially is this the case where, as in

the laboratory of the writer, the spectrograph, visual spectroscopes (prismatic and diffraction), and spectrophotometer are permanently set up in position for immediate use. The collection of dyes in colour-wedge form, with their accompanying photographic records ready for consultation, is obviously of inestimable value in many ways.<sup>4</sup>

In the testing of such a filter the first consideration is that of its influence upon the correct representation of the spectrum luminosity. A series of exposures was therefore made upon two plates, a Cramer "Trichromatic," and a Seed "27" bathed in pinacyanol. These negatives were then measured in the spectrophotometer and the curves plotted; in each case that spectrum selected for measurement gave as its maximum density<sup>5</sup> of 2.5 (Hurter and Driffield).

The best result, as will be seen from the curves, is obtained by the use of the pinacyanol-bathed plate, which was prepared in a bath of  $\frac{1}{500000}$  for a period of  $2\frac{1}{2}$  minutes, and followed by a washing of about 3 minutes; the plates bathed were Seed "27 Gilt Edge." The spectra obtained upon this plate leave little to be desired, but it would be obviously advantageous if use could be made of a com-

mercially followed one another; the entire time for both exposures being less than five minutes, the light meanwhile appearing constant. These plates were then developed together. The difference in exposure time necessary to obtain similar densities was then readily calculated from the distance apart of the plotted densities of the plates when measured, and was found to be for the Trichromatic and filter 9.2 times, and for the pinacyanol plate and filter 24.5 times. A number of subsequent exposures made in the camera confirmed these figures.

The absorption of the colour-filter was next measured by the spectrophotometer in the yellow-green ( $\lambda$  5500) and found to amount to 3.8 per cent.

The actual performance of the plate and filter in the telescope was determined by exposures upon objects of the class for which it was primarily constructed, viz., coloured stars. Figs. 3a and 3b show the long period variable *U Cygni* ( $\alpha = 20$  hr. 15 min. 7 sec.;  $\delta = +47^\circ 26'$ ), *B. D.* +  $47^\circ 3077$ , which is classified by Chandler<sup>6</sup> in his colour-scale as 9.3, "where 0 corresponds to white," and so on, "through increasing shades of intensity up to the deepest red

mercial plate already prepared and easily obtained. The "Trichromatic" was found to give very favourable results (Fig. 3), where the extreme red was not required, although the lowering of sensitiveness in the blue-green at  $\lambda$  5100 is still apparent, as will be seen from the measurement points on the mean curves.

In the series of varying time exposures upon this plate, it will be noted that the point of maximum intensity—i.e., highest luminosity—remains as a stationary point about  $\lambda$  5580, midway between the Fraunhofer lines D and E. In the "Purkinje phenomenon" the maximum (visual) luminosity, in strong illumination, lies close to this point, but shifts toward the more refrangible end of the spectrum as the illumination decreases, and finally, at near the point of extinction, lies in the blue-violet. This, however, is a purely physiological phenomenon and in no wise affects the real maximum as recorded upon the photographic plate. The point of strongest action therefore remains constant.

The increase in the exposure time consequent upon the selective filtration, as compared with that of the Seed "27," was determined by equal exposures made with the Hurter and Driffield revolving sector disk. The exposures were made to diffused daylight, and

of which we have cognisance in the heavens." In the eyepiece of the 24-in. reflector this star presents an extremely beautiful appearance, almost spectacular in effect. Mean visual estimations by Messrs. Parkhurst, Jordan, and the writer, on the evening of October 3, rate it as being possibly a trifle brighter than its neighbouring white star (*B. D.* +  $47^\circ 3078$ ), which is rated as of magnitude 8.3, and separated from it  $1' 35''$ . The photographic record of this intensely red star, as obtained upon the ordinary Seed "27" plate, shows it as far below its actual value; while, on the other hand, the beneficial effect of the filter and plate needs no comment.

The actual measurements of the disk diameters show that of the pinacyanol-bathed plate the red star is slightly larger compared with the white star, while on the "Trichromatic," owing to its less sensitiveness to the least refrangible end of the spectrum, the disk is of practically the same size.<sup>7</sup>

A further word may be said relative to the exposure through such a colour-filter as has been described, and which applies generally to all others. For definitely comparable results it is essential that the temperature and time of development, and chemical constitution of the developer, be kept as constants. This is so, then the only variable which enters into consideration

<sup>4</sup>All carefully measured filters made by the writer, such as those for the 40-inch Yerkes refractor, the Lowell Observatory, etc., have been derived in a similar manner.

<sup>5</sup>The development of all spectrum exposures is kept constant in constitution of developer, and time and temperature of development.

<sup>6</sup>Third Catalogue of Variable Stars, *Astronomical Journal*, 18, 145, 1896.

<sup>7</sup>Further and complete information relative to this work is shortly to be published by Messrs. Parkhurst and Jordan.

length of exposure. That this quantity must always be variable is unfortunately true, but to the worker of even limited experience the variance cannot be great, the trained observer being able to detect any decided "thickening" during the course of the exposure; this element of uncertainty obviously becomes greater as the exposure time is increased.

The influence of this variation upon the colour-correction is indicated by the graduated exposures in Figs. 2 and 3, and is self-explanatory. With increasing exposure up to that point which represents the true filter-multiple, the remainder of the photographic opacity increases about proportionately to that at the point of maximum sensitiveness at 45600; beyond this point the spectrum shows a tendency to spread out at either end. This is to be expected from the character of the filter where the absorption must be gradual and not in any way abrupt. This spreading (at the violet end) is a point, however, which need not be taken seriously, as it would require an exposure of about double the correct length of time to show any decided difference in the spectrum.

The drop in the reflectivity of the telescope mirrors as the silver films age<sup>8</sup> is a matter of no moment as affecting the relative exposure, as, for the work immediately under consideration, the screened exposure is always the same multiple of the unscreened plate, viz., 9.2 and 24.5 respectively. The tarnishing of the silver films ought, however, to be guarded against, as it exercises a more or less strong absorptive action upon the violet end of the spectrum according to the amount, and would thereby in critical work disturb the balance of action between the two sets of plates when taken at different periods.

It is a matter of some importance that the exposure multiple of the filter and plate over the Seed "27" be kept as nearly constant as possible, because, owing to the variance of the density-exposure curve of the plate with change in wave-length, a direct comparison of the faintest stars shown constitutes a very unreliable guide to exposure.

Although this filter has been made up primarily for use with a reflecting telescope in the work of photographic photometry, yet it will be plainly seen that its use does not end there. With the refractor it would be entirely unsuited, but with the ordinary high-grade doublet camera lens where all rays come to approximately identical focus, and on objects bright enough to allow for sufficient exposure, the gain in truthfulness of representation would be marked.

In conclusion, the writer begs to acknowledge his indebtedness to Messrs. Parkhurst and Jordan for exposures at the telescope and general interest in the work.

ROBERT JAMES WALLACE.

#### COLOUR WORK IN "PENROSE'S PICTORIAL ANNUAL."

THERE are 56 examples of colour printing, all of them, with the exception of one, being photo-mechanical in character. The one exception is that of the Aerograph Company, an example of stenciled printing, which can only be described as fearful and wonderful. It is hardly likely to recommend the method, in our opinion, to show such an example as this, and it is unnecessary as well, when the process can be made to give very fair results as shown by the supplement in the current "Photo-Engravers' Monthly."

The three-colour work, as shown by all the leading firms, both English and foreign, is excellent, and the English firms have nothing to be ashamed of by the comparison. There are several four-colours; most of them look a little heavy as compared with the three-colours, though there is one notable exception, a fine example of a vase in four-colour collotype.

The commercial colour work for catalogues, etc., appears to be best, and is a decided improvement upon that of previous years. There is much more relief in the work shown this year than hitherto, particularly noticeable in the vase mentioned above and in the four-colour example of an armchair. The three-colour tapestry, carpet, and edible articles are also notably good.

The most interesting colour work is perhaps the two-colour, one of the examples shown from "Pearson's Magazine," a drawing by Lewis Baumer, being quite delightful. It is certainly astonishing that photo-engravers and publishers do not attempt to get more of the very effective illustrations which appear to be possible by the use of only two printings.

Taken all together, the colour work shown is excellent, as indicating what is at present possible. The misfortune is that there is no indication how much of this is due to skilled hand work, and how much is due to the mechanical process. If we could only get some of the leading firms to show us some results before any fine etching, as well as their finished result, it would be extremely interesting to all those dabbling in colour work in every direction, as well as to those engravers not at present attempting colour, who might imagine from the results shown that photo-mechanical colour work is simple and all plain sailing.

#### SOLAR PRINTS.

THE following method of making this particular form of camera enlargement is given by Drs. Hildebrand and Feibus. The raw paper should be that specially made for this purpose by Steinbach and Co.

##### THE IODISER.

Acetic acid .....	97 cms.
Skim milk .....	2 1/2 litres.

Boil and filter. To 1 litre of the filtrate add:

Potassium iodide .....	33 gms.
Potassium bromide .....	8 gms.

The paper should be painted with a flat brush, or pad of cotton wool, with this solution, and dried quickly in a dark, warm place.

##### THE SENSITISER.

The dried paper is sensitised with the following solution, which is applied in the same way:—

Distilled water .....	500 gms.
Silver nitrate .....	42 gms.
Acetic acid .....	63 gms.

A deep yellow or red light is, of course, necessary. The paper should be exposed wet.

##### THE DEVELOPER.

Pyro .....	6 gms.
Acetic acid .....	80 gms.
Citric acid .....	6 drops.
Distilled water .....	1,000 ccs.

The print should be immersed in the above, and when sufficiently developed rinsed with water and fixed in a 1:8 solution of hypo for five or ten minutes.

The following method is also given, but it is a little more trouble:—

##### THE IODISER.

Sulphuric acid (pure) .....	57 gms.
Hydrochloric acid (pure) .....	15 gms.
Linseed (whole) .....	40 gms.
Water .....	2,000 ccs.

Boil and add:—

Sugar of milk .....	170 gms.
---------------------	----------

Then boil for half an hour, filter, allow to cool, and add:—

Cadmium bromide .....	22 gms.
Potassium iodide .....	74 gms.
Cadmium iodide .....	22 gms.
Water .....	500 ccs.

Then add:—

Mercuric chloride .....	1.5 gms.
Water .....	200 ccs.

##### THE SENSITISER.

Silver nitrate (pure) .....	10 gms.
Nitric acid .....	1 drop.
Water .....	1,000 ccs.

##### THE DEVELOPER.

A.—Pyro .....	25 gms.
Citric acid .....	25 gms.
Water .....	2,000 ccs.
B.—Eikonogen .....	10 gms.
Potassium metabisulphite .....	5 gms.
Hot water .....	2,000 ccs.

For brilliant negatives 1,000 parts of A with 10 parts of B. Increase of B. gives soft results and reduction, harder results. The temperature of the developer should be 104 deg. Fahr., and may be stopped

<sup>8</sup>C. A. Chant, *Astrophysical Journal*, 21, 211, 1905.

by immersing the print in cold water or a 5 per cent. solution of common salt. For fixing, a 1:3 solution of hypo should be used, and the prints left therein for one hour. Iodised paper will keep for a month in a cool dark place. In order to save the silver solution it should only be applied to that part of the paper on which the image is to appear. With a little experience and care  $\frac{1}{2}$  gm. = (7 $\frac{1}{2}$  grains) of silver nitrate will suffice for a sheet of 50 x 60 cm. (= 20 x 24 inches).

#### THE LATE J. T. SANDELL.

MR. SANDELL'S death, announced in our last issue, has not altered the need of the fund to which many of our readers contributed, and in reference to which the sums sent to Mr. Thos. K. Grant have been acknowledged in our columns. Mr. J. B. B. Wellington, to whom also a large number of donations have been sent, now sends a complete list, from which we select for publication those which have not been previously acknowledged in our columns. It need scarcely be said that Mrs. Sandell is left without support other than that of friends, and though the burden of an invalid husband has been lifted from her, the maintenance of a family the eldest of whom is sixteen years, still devolves upon her, and therefore any further donations will be thankfully received by Mr. Grant or Mr. Wellington, or sent to them by ourselves. The list, abbreviated as already specified, runs as follows:—

Fred Schofield .....	£0 5 0

#### HOW MR. BENEDICT HERZOG WORKS.

THE figure studies of the clever New York amateur photographer, Mr. F. Benedict Herzog, is the subject of the critique in the current "Camera Work," in accompaniment of the reproduction of two of Mr. Herzog's marvellous studies of line. The writer of the critique assuming that the figures in Mr. Benedict's photographs are posed as they appear, the editors append a description of an actual composition. As a matter of fact, Mr. Herzog proceeded approximately as follows:—Having made innumerable single or occasionally double-figure studies on 4 x 5 plates, and having made bromide enlargements from each of these negatives, and having from these enlargements cut out the figures, paper-doll fashion, he then proceeded on a large panel, and with these figures and a paper of pins, to group and re-group, arrange and re-arrange—in short, carry on experiments in his "hunt for the line!" When finally the composition satisfied his eye, he pasted down the pinned figures, and with brush and pigment filled the gaps and pulled together the sections of his composition. Lastly, he photographed this result in various sizes, thus producing a number of "original" negatives.

#### DEATH OF MR. S. D. MCKELLEN.

It is with much regret that we have to announce the death of Mr. S. D. McKellen, of Manchester, which took place on December 26, shortly after an operation for a serious internal complaint. The present generation of photographers may or may not be aware of the fact that Mr. McKellen was the father of the modern camera. Photographers of twenty years ago will well remember the advent of the McKellen Camera in 1884, when it obtained the first medal for apparatus ever offered by the Photographic Society of Great Britain (now the Royal Photographic Society), and how it entirely revolutionised the construction of this instrument.

Mr. McKellen first commenced photography upwards of fifty years ago with a cigar-box and spectacle lens as his apparatus. Since then his photographic experiences with the wet plate apparatus—where a pony and cart had to be obtained to carry one's paraphernalia about, and later with a 15 in. by 12 in. McKellen camera, and three double slides (before the days of small plates and subsequent enlarging)—were always worth listening to, and one can only think that they were enthusiasts in those days. Mr. McKellen was seventy years of age at the time of his decease.

#### Photo-Mechanical Notes.

MESSRS. JOHN SWAIN AND SON, LIMITED, have made a step forward in installing the Levy acid blast etching machine in their establishment, and have issued an illustrated circular showing the remarkably sharp results obtainable by the blast method of etching. The process is designed specially for the making of newspaper half-tones, and newspaper men who may think of using such on a large or small scale are invited to witness a demonstration of the process at Messrs. Swain's factory, 58, Farringdon Street, London, E.C.

#### Multi-Colour Prints in Grain.

The speed of typographic blocks with the quality of lithographs are the aims of an inventor of a multi-colour printing process for which an English patent (No. 4,476, 1906) has been granted. The inventor, Mr. John Bachmann, 355, New York Avenue, Jersey City, U.S.A., designs to employ the process particularly for catalogue work, labels, etc., although it is intended for any purpose for which good colour work is desired. The process consists in:—

1. Making photographic negatives of the originals through colour filters.
2. Making positives from these negatives on gelatine plates, sensitised with bichromate, and printing in the required colours from these plates.
3. Treating these prints to give them a lithographic grain and preparing negatives from the prints, and from the negatives actual printing plates.

The printing plates referred to in (2) are made by coating ground glass plates with a substratum of porter and caustic potash and

silicate of soda, the last applied immediately after the mixture of the first two. After drying, the plates are rinsed in water (to remove glucose derived from the porter), and given a coating of:—White gelatine, 50 parts; potass. bichromate, 15 parts; chrome alum, 1-15 part; water, 500 parts. After coating the plates are baked.

The exposure of these colour plates under the negative is the stage in the process during which the texture is developed into a printing possibility. Before exposure the plate is again placed in the oven in which it is baked, but before doing so a pan with water is put in the bottom of the oven for the purpose of creating moisture. Heat is applied and the temperature brought up to 100 deg. Fahr. When the plate has become warm in the moist atmosphere, which will require about six minutes, it is ready to be exposed under the negative. The print is complete when the deepest shadows have a transparent appearance. After this the plate is taken into the dark room and washed in running water to remove the chromate, then taken out of this room and dried. Before printing from the gelatine plate with printing ink the plate must first be dampened for about 15 minutes with a solution composed of 500 parts of water, 400 parts of glycerine, 50 parts of ammonia, and 50 parts of common salt. The plate is now put on the press and rolled over with a leather roller charged with black ink. The image will soon begin to show, and when it has developed, or its values appear to the eye in the form of black printing ink to the required extent, then the paper can be laid directly on the plate and an impression drawn. Upon inspection of this impression it will be found to be of a fine open grain in texture. It becomes closer approaching the shadows and absolutely solid black where the colour in the original copy is deepest.

From such described plates, charged with black printing ink, impressions are now drawn on white paper or cardboard. Assume that a job has to be done which requires three of the final metal printing plates of one colour, say blue. In order to get them we employ the following method:—The gelatine plate which has been exposed under the blue negative is moistened with water containing ammonia, and rolled over with a leather roller charged with the stiffest of black ink. The very deepest parts of the image of the plate only will take the black printing ink, and as the deepest blue on the copy corresponds with these parts of the plate, it is natural that an impression drawn therefrom will represent that value in black. For the medium blue less stiffened ink, we roll longer and use less ammonia in the dampening water. For the pale blue, soft ink is used, no ammonia in the dampening water and rolling until the last possibility in the plate is developed, or made visible in the form of black printing ink.

To obtain a litho grain, after all the required impressions from the gelatine plate are drawn in black, this plate is washed clean with turpentine, and the same is again rolled over with a roller charged with a pale blue ink of such consistency as will allow itself to adhere to the entire image on the gelatine plate. From this so inked plate, with light blue colour, an impression is once more drawn on the same sheet that has already been printed in black from the gelatine plate. Care must be taken that it will register exactly to the one in black; it is easily done by the use of pointing needles. This blue print is necessary for a guide and retouching the prints in black, and as this, which may be called a key, is in light blue colour, this colour will have no effect upon the negative, which must later on be taken from the black prints.

The black prints from the chromate gelatine plate with the blue key now pass to the hand of a man known as a stippler, whose task is to join his art to the existing texture found in the black prints from the gelatine plate. This can be done with a pen, brush, or whatever may be found most practical to give the prints the ear-mark of lithography.

From these prints drawn from the chromate gelatine plates, and treated by the stippler to give them the ear-mark of lithography, negatives are now taken preferably by what is known in photography as the wet plate process. After the print has passed the hands of the stippler the negative is taken from the same; its use is explained further down. When this has been done the same print is taken again and printed from the chromatic plate, the value of the medium shade whereby the print in the darker parts will be intensified. This leaves only the extended medium shades to be treated by the stippler. We now take a negative of this print and proceed in the described manner with the next shade, thus obtaining the three negatives practically from the one positive.

Typographic colour plates on copper are now made with a sensitiser of bichromated albumen fish glue, and etched first in a bath consisting of ferric chloride, 16 gr.; water, 80 ccs.; gum arabic, 20 gms.

## Exhibitions.

### WISHAW PHOTOGRAPHIC ASSOCIATION.

WISHAW Exhibition is a New Year one, and runs from the one year to the other, making its mark in the New Year celebrations of the district. On its opening night one can be almost certain of meeting some of the leading photographic lights of the vicinity. There one had the pleasure of meeting Charles Reid, of Wishaw, known to all country folks and photographers as the animal photographer. Reid o' Wishaw must be one of the first specialists, and he has specialised to some purpose. How many prize horses, sheep, cattle, etc., he has photographed it would be difficult to say; in fact, it would be easier saying what celebrated animals he had not photographed. All over Britain has he found food for his camera, and as indicating the universality of his pictures it might here be stated that they are not only popular with the experts of the breed depicted, but they are also popular with the general public, as proved by a clearest of proof—they sell.

From his studio near by came Dan Dunlop on the opening day. It is difficult to say what his particular line is; he has not yet settled down; he is still in the butterfly stage, flitting about from one thing to another, and, perhaps unfortunately, doing well in them all. He must have medals and awards for nearly every phase of photography, with perhaps the exception of micro-photography and astronomical photography, but one never knows. Debonair and dainty, as one of his birch tree studies—Dan, as he is frequently called, is a "hail-fellow-well-met" with all acquaintances.

The open classes of the Exhibition do not seem to have received much support from the profession, the only known name being G. L. A. Blair, Paisley, who, with "Little Venice," takes first place in the Federation Class.

In the invitation section, however, the profession monopolises the walls. Wm. Crooke has a trio of his "grand" portraits on view—Kate Wiggin, Brough the artist, and his celebrated Irving; J. Craig Annan shows "On the Thames at Hampton Court" and "Stirling Castle," with its full rich shadows; Dan Dunlop shows "Pensive," his most recent success; J. M. Whitehead sends three examples of his peaceful, poetic landscapes; John Patrick is represented by his great portrait of Carlyle; James Patrick (who judged the show), has, amongst others, "A Stilly Hamlet Home," etc. and "Light at Eventide"; John Moffat shows his dainty, "The Dance," while Reid o' Wishaw sends some of his more popular animal studies. He also helped the show by lecturing on "Our Animal Friends."

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between December 24 and 31:—

**CINEMATOGRAPHS.**—No. 29,333. Method of producing and exhibiting cinematograph pictures in such a manner that they are seen in the colours of the original. Edward Ferdinand Grün, The Hall, Southwick, Sussex.

**STEREOSCOPES.**—No. 29,419. Improved stereoscopic apparatus. August Fuhrmann, 322, High Holborn, London.

**LENSES.**—No. 29,446. Improvements in photographic objectives. Carl Zeiss, a body corporate, Jena, Germany.

**LENSES.**—No. 29,447. Improvements in photographic objectives. Carl Zeiss, a body corporate, Jena, Germany.

**CATATYPE.**—No. 29,480. Process and apparatus for converting silver pictures into platinum pictures having catalytic power. A. G. Bloxam, Southampton Buildings, Chancery Lane, London, for the Neue Photographische Gesellschaft, Berlin.

**SHUTTERS.**—No. 29,487. Improvements relating to exposure shut-

ters for photographic cameras. Harold Walter Pearn, 18 Southampton Buildings, Chancery Lane, London.

CAMERAS.—No. 29,580. Improvements in photographic cameras. Arthur Lewis Adams, 26, Charing Cross Road, London.

LAMPS.—No. 29,616. Improvements in or relating to electric mercury vapour lamps. Robert Hopfelt, 110, Gitschiner-strasse, Berlin, Germany.

LENSES.—No. 29,640. Improvements in photographic lenses. George Lindsay Johnson, 322, High Holborn, London.

#### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

DEVELOPING MACHINE FOR ROLL-FILM.—No. 25,857, 1905. The invention consists of an apparatus for daylight development of roll-films, containing a "two-roller" system, working in a trough provided with means of inspection. The trough *a* resembles the back part of an ordinary folding roll-film camera of the usual type. The open top corresponds to an aspect viewed from the inside of the camera. At each end of the trough are pins *b*, *b*, on which the spools *c* can turn, but for each spool there is a turning or driving device. The ends of the trough are formed with wells *a*<sup>1</sup>, *a*<sup>1</sup>. The exposed spool having

Fig. 1.

been placed on the pins at one end of the trough, an empty spool is placed on the pins at the other end. A sufficient length of the protective black band *d* is then unrolled to enable the end to be passed through the slot (not shown) in the core of the uncharged spool.

Developer is poured into the trough *a*, the band of protective backing is wound on the uncharged spool, and with this band the sensitive film also travels. At this stage or a little later, the fluid first poured in may be suitably modified. If the operation has been commenced with plain water a powder containing suitable developing chemicals may be sprinkled in or added; or a strong solution of such chemicals may be added.

By the method described above, and assisted by the regular

Fig. 2.

shape of the trough, also by the brush or flap described below, a film of liquid is induced and retained by capillarity in the convolutions of the roll, thereby obviating the necessity of introducing what is known as an "apron" or separator between the convolutions during the process of development.

The trough is covered with a closely fitting lid *a*<sup>3</sup> carrying one or more red windows *a*<sup>4</sup> for viewing the progress of development, and has means such as indicated at *a*<sup>5</sup> for pouring in liquid without exposing the film to daylight. That portion of the trough between the well portions *a*<sup>1</sup>, *a*<sup>1</sup> and across which the film travels may be made with a raised bottom or be less deep as shown at *a*<sup>6</sup>, and the cover *a*<sup>3</sup> may be recessed over this raised portion *a*<sup>6</sup> as indicated at *a*<sup>7</sup>. This recessed portion

of the cover is found to be a convenient position for the non-actinic inspection window *a*<sup>4</sup>, but a hinged flap *a*<sup>8</sup> should cover this window. On one side of this recess is attached the inflow funnel *a*<sup>5</sup> and at a convenient point in the bottom of the well or wells a tapped outflow *a*<sup>2</sup> is provided.

The other mechanical details of the developing machine are described at length in the specification. William Fraser Cloughton Kelly, 8, Perham Road, Kensington, S.W., and Thomas Bolas, 60, Grove Park Terrace, Chiswick, S.W.

FLASH-LAMP IGNITION.—No. 6,705, 1906. The invention consists in the particular combination of a source of current with an induction device, whose circuit is closed and opened by actuating the instantaneous shutter, and in which an induced current is made in the secondary circuit which may consist of two or more parallel circuits. The secondary circuits are interrupted at the spots in which the flash lamp is to be ignited and the flash light powder is ignited directly or indirectly by the spark of the secondary current, which is high tensioned as compared with the primary current springing over at that spot. The arrangement of the source of current and induction device and flash-lamps may be any which is desired, and can be altogether independent of the photographic apparatus, the actuating device being connected with the instantaneous shutter. Wilhelm Venier, Jenullgasse, 17, Vienna.

EXPOSING PLATES AND FILMS.—No. 4,992, 1906. This invention consists in improvements in the exposing chamber of Specifications Nos. 10,097, 1904, and 15,953, 1905. The chief claims are:—

1. In adapters or dark slides for exposing photographic plates or films, the combination of a frame, a sliding door having a wedge-shaped inner end to enter a V-shaped groove in the frame, and a hinged door fitted with a spring-connected focussing frame and a hinged shutter therein fitted with side pieces to act as a folding hood.

2. In adapters or dark slides for exposing plates or films in the camera, the combination of a hinged door fitted with a hinged shutter, side pieces to act as a hood, and a spring-supported focussing plate.

3. In light-tight envelopes for carrying photographic plates (Specification No. 10,037, 1904), a block or bar or alternatively corner pieces within the end groove of the inner envelope in combination with a block on same.

4. In light-tight envelopes for carrying plates or films, forming the sliding paper cover of the inner envelope with side wing pieces, and folding the same over the edge of the inner envelope before inserting the same in the outer envelope. George Wishart, High Bushyhill, Cambuslang, Scotland.

VIEWING PANORAMIC PICTURES.—No. 16,917, 1906. An instrument for properly examining a completely circular panoramic photograph is constructed as follows:—

A total reflection prism *a* (figs. 1 and 2) is placed as indicated in the drawing within the panorama *c*, *d*, *e* with its longitudinal

Fig. 1.

Fig. 2.

edges parallel to the diameter of the circle *c*, *d*, *e* and the centre of its hypotenuse lying on the axial line of the panorama or substantially so. The portion *c* *d* of the picture is reflected by the prism and a vertical image symmetrical with the actual picture is formed with regard to the plane of the hypotenuse of the prism. A line, *g*, *h*, for example, of the actual image is seen at *i*, *j* (Fig. 1) by the observer placing his eye in front of the prism at a point *k* exteriorly of the panorama. There is interposed between the eye of the observer and the prism a biconvex lens *b*, the purpose of which is simply to magnify the virtual image seen by the eye from the point *k*.

The different parts forming the apparatus are secured in

the required place by supports arranged in any suitable manner.

The more the longitudinal edges of the prism  $\alpha$  are extended the larger will be the portion of the reflected picture.

All the different parts of the cylindrical panorama may be successively viewed by rotating same about its horizontal axis. Société Anonyme Périphote et Photorama, 33, Rue Joubert, Paris.

**CAMERA FRONTS.**—No. 17,092, 1906. The invention consists of a mechanism by which the front and back of a camera are maintained parallel and upright during the opening or closing of the instrument.

The movement of the mechanism is not easy to describe without the numerous diagrams, but consists in the attachment to the front of the camera of a sliding bracket, a lever on which, pivoted to the bracket, is caused to actuate the stretcher of the camera front as the baseboard is moved upwards to close the camera. As the board is raised the lever on the bracket pushes the stretcher outwards so that the movement of the baseboard is compensated and the camera front remains upright. The object of the movement is not stated. The Thornton-Pickard Manufacturing Company, Ltd., Altrincham, George Arthur Pickard and Frank Slinger.

## New Trade Names.

**WATALU.**—No. 287,937. Sensitised photographic plates, sensitised photographic films and all other photographic materials included in Class 1. The Self-Developing Plate Company, Limited, 7, Southampton Street, Bloomsbury, London, W.C. Manufacturers and dealers in photographic materials. November 15, 1906.

**BOROXYLITE.**—No. 287,954. Chemical substances used in photography. Siebe, Gorman and Co., Limited, 187, Westminster Bridge Road, London, S.E. Submarine Engineers. November 15, 1906.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### What to Leave Out?

THIS, says Mr. Arthur Guest in "The Amateur Photographer," is often one of the most puzzling problems that the artist has to solve, and the more sensitive he is to the beauty that surrounds him, the more painful becomes the duty that he knows he must fulfil, of ignoring some of the fascinating life that, modestly or coquettishly, sometimes even vociferously, beckons his attention. In one way it is a great help to regard everything in Nature as alive, a conception justified by the scientific dictum that atoms are in perpetual movement, and one that enforces the expressiveness of so-called inanimate objects, and so tends to obviate dullness in a picture. But this standpoint only intensifies the regret at the ruthless abandonment of silent things that have made their appeal and convinced us of their charm. "Yet art is, and must always be, one long story of sacrifice, and unless these claimants on our sympathy can show their usefulness to the end that we have in view, their call will be callously disregarded—or, perhaps, noted for response on a more appropriate occasion. We must harden our hearts; for if we give way to these charmers the result is bewilderment, and diversion from our main purpose.

### The Real Outdoor Photography.

"A Painter," writing in "Photography," says:—"More study of Nature and more study of pictures is what we all want. The photographer is tempted to scamp his Nature study, because his process gives him his complete picture so quickly, and even then most of the short time it takes is time spent away from his subject. I do not know how far it would be practicable, but I should like to see a photographic study which had had all its handiwork put on it by the photographer in full view of his subject. It might possibly be no better, but the training which such a system would give the photographer himself would be quite invaluable."

## Orthochromatic Photography.

Mr. Arthur Payne, F.R.P.S., in "The Photographic News," waxes warm on his favourite topic of orthochromatic photography, a term which he anticipates will extinguish itself by the very popularity of colour-sensitive plates, the public being represented as coining the term "blue-sensitive" for plates of the present-day "ordinary kind." Mr. Payne concludes by mentioning a curious fact:—

"I wish to mention that for some as yet unexplained reason it is necessary to develop the orthochromatic plate when used without the light filter for a longer time than when the light filter is used, in order to get the same degree of contrast in the negative, and consequently in the print."

### Still Life Subjects.

"The lighting of still life studies" (says Mr. Henry Walker in "Focus") "is a factor of the greatest importance. Where resort cannot be had to a studio, and where the work must, forsooth, be done in an ordinary room, considerable difficulty will be experienced in securing satisfactory lighting. Cross lighting is to be preferred, with the use of a reflector to soften the shadows. If there is much top light from the window it should be cut off entirely, and if the light from the lower portion is very strong it should be subdued by the use of a sheet of tissue paper. The mistake is usually made of placing the subject too near the window, with the result that the shadows come out heavy, and the high lights chalky. Further from the window the light is more subdued, and if a reflector, made by throwing a sheet of white paper over a clothes-horse, be placed so as to illuminate the shadows, the tone values will be preserved."

## New Books.

"Camera Work." No. 17. Edited and published by Alfred Steiglitz, New York.

As usual this sumptuous magazine is filled with plates that are all of them interesting, if not quite all beautiful; and its literary matter is keenly and learnedly critical, and therefore valuable.

Of the pictures, the first one, "Leonore," is the best. It is one of a set of six by Mr. Joseph T. Keiley, and is a delightfully soft and rich presentment of a handsome maiden seated upon the floor. We should like to get rid of the ugly lines made by the carpet edge; beyond this trifle we have nothing but praise. A portrait of "Miss De C." is likewise a work of much distinction. Its posing is admirable, and the character in the sitter's face a pattern and lesson to all portraitists. Two crowded compositions by F. Benedict Herzog, "The Banks of Lethe" and "Twixt the Cup and the Lip"—of which we prefer the latter, because it is simpler in interest and larger in style—accompany an article from the pen of Charles H. Caffin. Mr. Caffin is by no means an admirer of the work of Mr. Herzog; but the reasons he gives for this antagonistic attitude do not win us over to share his views. His attitude is that of one who can only believe in the present and the promise of the future. He appears to think that because certain notions of decorative art were held in past times they have therefore been superseded. Such a view of art is perhaps indigenous to America. Personally, we think there is much more Art (writ large) about the best of Mr. Herzog's Veronese-y compositions than some of the up-to-date strivings after passing phases of painting, which are in reality much less within the scope of the camera. "In the Circus," by H. C. Rubincan, is a great triumph.

Mr. Fredk. H. Evans has an article upon last year's English Salon. It will be understood that we cordially endorse his sentiments of disappointment when we say that his remarks practically reproduce our own when we reviewed the same exhibition.

We are glad to see signs of a solid commercial prosperity about "Camera Work" in the shape of plenteous advertisements in the present number.

A NEAT piece of photographic evidence was produced in a Norfolk police court last week. The owner of a cart was brought up on remand for failing to have his name painted on his cart. He alleged that the whole name was legible. A photograph produced in court, however, showed certain letters brighter than others owing to their recent addition. The owner was fined 15s. and the costs of the photographs. He now wishes he had engaged Dr. Mees for his defence.

## New Materials.

New Mezzo-Tint Paper. Made by Marion and Co., Limited, 22-23, Soho Square, London, W.

In this printing paper the makers have evidently set before themselves the production of a print which should have an appearance both handsome and out of the common, and that they have achieved this end without burdening the user with anything beyond the usual manipulation is matter for congratulation. The paper is toned in a platinum bath exactly like P.O.P., the formula of the makers being the well-known mixture of citric acid, salt, and potassium chloroplatinate. In this bath we found the paper to tone to a fine sepia colour. There is little weakening of the prints in toning and fixing and only the slightest over-printing should be done; less, we think, than with the average P.O.P. The surface of the prints is a matt, with just a shade of semi-gloss, the latter noticeable only in the shadows, where it relieves the prints of a choked-up appearance. We are glad to have the opportunity of introducing the paper, particularly to our professional readers, to whom it will undoubtedly appeal as a paper permitting of fine effects by very simple means. We can imagine that a very attractive line of portraits might be done in mezzo-tint printed with a white margin and issued in a folder. Messrs. Marion do, indeed, recommend and supply folders as effective settings for the prints, and the hint is worth taking. The price of the paper is 5s. 6d. for 72 half-plate pieces.

### FORTHCOMING EXHIBITIONS.

1907.

January 14 to 26: Royal Institute of Fine Arts.—Sec., J. Lizans, 101, Buchanan Street, Glasgow.

January 18 to 31: Paisley Philo. Institute and Photographic Society.—Sec., Hugh F. Hamilton, Glaisnock, Bank Street, Paisley, Scotland.

January 23 to 25: Dover Photographic Society. Secretary, J. W. Howells, 6, Gladstone Terrace, Dover.

January 24 to 26: South Essex Camera Club. Entries close January 17.—Sec., T. Mitchell, 180, Browning Street, Manor Park, E.

January 31 to February 1: Isle of Wight Photographic Society. Entries close January 17. Sec., H. G. Morgan Hobbs, Sunnyside, Watergate Road, Newport, I.W.

January 31 to February 2: Nelson Photographic Society.—Sec., Henry H. Beetham, 98, Brunswick Street, Nelson.

February 6 to 7: Cowes Camera Club. Entries close January 23.—E. E. Vincent, 4, High Street, Cowes, I.W.

February 7: Borough of Tynemouth Photographic Society. Entries close January 25.—Sec., J. R. Johnstone, 159, Linskill Street, North Shields.

February 11 to 14: Cripplegate Photographic Society.—Sec., J. B. Parnham, "Chagford," Old Church Road, Chingford.

February 12 to 23: Sheffield Photographic Society. Entries close January 26.—Sec., J. W. Wright, 62, Vale Road, Sheffield.

February 13 to 15: Northern Tasmanian Camera Club.—Sec., F. Styant-Brawne, 112, Brisbane Street, Launceston, Tasmania.

February 15: Cardiff Photographic Society.—Hon. sec., A. E. Harris, 44, Partridge Road, Cardiff.

February 20 and 21: Royal Albert Institute, Windsor.—Hon. Sec., Mr. J. W. Cooch, 9, High Street, Windsor.

February 20 to 21: Canterbury Camera Club. Entries close February 9.—Sec., G. T. Hobbs, 3, Norman Road, Canterbury.

February 22 to March 4: Norwich and District Photographic Society.—Sec., J. T. Tanner, The Lodge, Norwich.

February 23 to March 2: Birmingham Photographic Society.—Sec., Lewis Lloyd, Norwich Union Chambers, Birmingham.

February 23 to March 9: Edinburgh Photographic Society. Entries close February 9.—Sec., H. Stewart Wallace, W.S., 77, George Street, Edinburgh.

February 25 to 28: Worthing Camera Club. Entries close February 16.—Sec., E. F. H. Crouch, 11, South Street, Worthing.

February 26: Norwich and District Photographic Society. Entries close February 12.—Sec., J. T. Tanner, The Lodge, Bowthorpe Road, Norwich.

February 27 to March 2: Nottingham Camera Club. Entries close February 14.—G. R. Cranch, St. Jude's Avenue, Nottingham.

March 2 to 9: South London Photographic Society.—Sec., W. L. White, Bank House, Ladywell, London.

March 6 to 9: Wearside Camera Club. Entries close February 20.—Octavius C. Wilmot, 297, High Street West, Sunderland.

March 6 to 9: Bolton Amateur Photographic Society. Entries close February 16.—Sec., Gilbert Holt, 187, Deane Church Lane, Bolton.

March 7 to 16: Leicester and Leicestershire Photographic Society. Entries close February 16.—Sec., Lewis Ough, "Fernleigh," St. James' Road, Leicester.

March 14 to 23: Leicester Photographic Society.—Sec., W. Murray, 60, Melton Road, Leicester.

March 22 to April 13: Northern Photographic Exhibition.—Sec., C. F. Inston, 25, South John Street, Liverpool.

April 17 to 19: Belfast Y.M.C.A.—Sec., J. W. Bushey, Y.M.C.A. Camera Club, Belfast.

April 29 to May 14: Photographic Society of Ireland.—Sec., R. Benson, 35, Molesworth Street, Dublin.

### CATALOGUES AND TRADE NOTICES.

WYNDHAM AND CO., LTD., Printers, Bollo Lane, Acton, W., send a circular giving particulars of the special cash terms which they are now offering for colotype postcards from customers' prints. Messrs. Wyndham's work, which is of a high class, merits the notice of readers who have orders of this kind to place. The firm also prints in bromide and P.O.P., and in other respects is able to supply the printing and illustrating requirements of photographers.

THE Art Photographic Supply Co., a firm which has made a specialty of enamels, send us two charming examples of their latest work. They supply these enamels not only unmounted but complete as gold pendants, lockets, bracelets, etc., at prices which both for the unmounted and complete work appear to us extremely moderate. The illustrated circular, obtainable from Grosvenor Buildings, Steelhouse Lane, Birmingham, will give particulars of the prices and styles.

THE Tress Co., 42, Oxford Street, W., send us their catalogue of professional specialties, including the Tress gas lamp and styles of enlargement. The firm's goods are very moderately priced.

The Rotary Photographic Company have issued a 1907 list of their numerous specialties, bromide, and gaslight papers, carbon films, etc., in waistcoat-pocket size, which should prove a convenience to their many patrons.

A new catalogue of frames, specially offered to photographers reaches us from Mr. Fred W. Forbes, of 11, Clerkenwell Green, London, E.C. Mr. Forbes, who is an actual wholesale maker, produces a large variety of frames, shelf frames, overmantels, hat-peg frames, etc., and makes a specialty of Rococo styles, of which he has shown us several attractive specimens. His list, which runs to twenty-four pages and is fully illustrated, should be worth getting.

MESSRS. ALFRED AND J. KNUTTON, who have hitherto represented Mr. William Tylar, of 41, High Street, Aston, Birmingham, are no longer connected with that firm, and Mr. Tylar asks that in future orders may be sent to him direct at the above address.

A SEAMAN of Penzance, dressed in the uniform of the Royal Marines, unlawfully appropriated the sum of £9 belonging to a master mariner of the same town. He was arrested in London, and though passing under an assumed name, was identified by means of his photograph which was in the possession of the police. This is another proof of the valuable aid which photography renders in the cause of justice.

THREE-COLOUR Prints.—Re the frilling up and separation of the three-colour carbon prints (writes Mr. Hamilton Smith), I think your correspondent, "Trichrome," will not be troubled with the frilling if in mounting the finished print he binds the edge of print with a strip of art paper similar to a lantern slide. I use this method and have no trouble.

"OUR NAVY."—Mr. West, whose popular cinematograph show, "Our Navy," continues to attract audiences to the Regent Street Polytechnic building, is now on his way to the West Indies to obtain fresh material for the "Our Colonies" part of the entertainment.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, JANUARY 11.

Loughton Photographic Society. "Enlarging on 'Rotograph' Bromide Paper." Rotary Company.  
 Sutton Photographic Club. "Platinum Printing." Demonstrated. A. Werner, F.R.P.S.  
 Aberdeen Photo Art Club. "Pictures with the Goetz Lens."  
 Sutton Photographic Club. "Toning Bromide Papers." A. P. Hoole.  
 Hampstead Scientific Society. "Timber, and Some of its Diseases." Mrs. Plomer Young  
 Cardiff Photo. Society. "Bird Holidays in Pembrokeshire." J. J. Neale.

MONDAY, JANUARY 14.

Southampton Camera Club. "Memories of a Mighty Marshland Minster." H. W. Harvey P. Per.  
 Derby Photographic Society. "English Cathedrals."  
 Preston Camera Club. Demonstration by Messrs. J. and J. Griffin, London.  
 Oxford Camera Club. "British Birds and their Nests." Mrs. Veley, Dec.  
 Leek Photographic Society. "Toning P.O.P." Demonstrated. Mr. F. Bradley.  
 Leamington Photographic Society. "Pinatype."  
 South London Photographic Society. "Architectural Photography." E. R. Bull.  
 Aldershot and District Camera Club. "Enlarged Negative on 'Rotograph' Negative Paper."

TUESDAY, JANUARY 15.

Royal Photographic Society. "The Beauties of the Higher Alps." Louis J. Steele.  
 Wigan Camera Club. "Tabloid Brand Photographic Chemicals."  
 Reigate and District Photographic Association. "Wensleydale." F. Brandrett.  
 Holmleigh Photographic Society. "English Ecclesiastical Architecture." C. B. Hoell.  
 Hackney Photographic Society. "Photographic News Slides."  
 Darlington Camera Club. "Toning Bromides." R. Borrow.  
 Manchester Amateur Photographic Society. "The Scottish Photographic Federation Folio." Dr. A. T. Lakin.  
 Salisbury Photo. Society. "Enlarged Negative on 'Rotograph' Negative Paper."  
 Altrincham Photographic Society. "Theory and Practice of Self-Toning Paper." John J. Griffin & S. R. Borrow.  
 Birmingham Photographic Society. "Ozobrome." James Gale.

WEDNESDAY, JANUARY 16.

Edmonton Photographic Society. "Latest Kodak Productions."  
 Cambridge Wells Amateur Photographic Association. "Figure Study." E. T. Holding.  
 Everton Camera Club. "Recent Advancements in Photography." Demonstrated. H. Wade.  
 Woodford Photographic Society. "Forest Life." Martin Duncan.  
 Croydon Camera Club. "Odds and Ends, or Useful Hints from Members."  
 Borough Polytechnic Photographic Society. Third Lantern Slide Competition.  
 Southsea Photo. Society. "Postcard Photography on 'Rotograph' and 'Rotox' Postcards."  
 Birmingham Photographic Society. "Enlarging and Printing on Bromide Paper."

THURSDAY, JANUARY 17.

London and Provincial Photographic Association. "A Trip to the Victoria Falls of the Zambesi." J. K. East.  
 Chelsea and District Photographic Society. Lantern Evening—Affiliated Slides. 1905.  
 L.C.C. School of Photo-Engraving. "Etching Proper, Photo-mechanical Etching and Fine Etching." A. H. Tinkler.  
 Handsworth Photographic Society. Lantern Exhibition. "Photographic News Prize Slides."  
 Liverpool Amateur Photographic Association. Annual Meeting and Members' Exhibition.  
 Hull Photographic Society. "Further Experiments in Toned Bromides." F. J. Webb.  
 Bristol Photographic Club. "Stories and Glories of Westminster Abbey." E. W. Harvey Pper.  
 Chichester Photo. Society. "Enlarged Negatives on 'Rotograph' Negative Paper."

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held January 8, Mr. A. Haddon in the chair. A brief reference was made to the loss sustained by the society in the death of Mr. Thomas R. Dallmeyer.

A paper on the "Action of Substances upon the Latent Image," by Dr. S. E. Sheppard and Dr. C. E. K. Mees, was read by Dr. Mees. The first part of the paper dealt with the action of chromic acid upon plates, with especial reference to the theory of primary and secondary development put forward by Mr. Sterry in January, 1904. This theory suggests that the primary image formed by the development of the "latent" image is intensified by silver transferred from other parts of the film. The authors found that exposed plates, dipped in chromic acid solution before development have their  $\gamma$  and inertia unaltered, but the development velocity constant K lowered by the action of the chromic acid absorbed to the silver bromide. This chromic acid could be destroyed by sodium sulphite, and the plates then gave a normal K. If, however, a plate was left after chromating, before development, a fall in  $\gamma$  was found, which could not be destroyed by sulphiting, and which, therefore, showed an absolute destruction of the latent image. Probably this action was a re-oxidation process.

The second part of the paper dealt with a peculiar action of salts

of copper, iron, mercury, and uranium which desensitise the plate, so that enormous exposures are required to produce normal results. If the plates were exposed and developed after desensitising, K and  $\gamma$  were found to be normal. If, however, the plates were left for a long period after exposing, then the desensitisers destroyed the latent image by lowering  $\gamma$  in the same way as chromic acid. The theory advanced for this action was that desensitisers act by catalysing the acidation reaction, which is the opposite to the ordinary light reduction reaction, and this view was supported by experiments, which showed that with copper, quinine salts, and with iron, oxalates restored the lost sensitiveness, a result analogous to that obtained for the negative catalysis of quinine in the case of the catalysis of sodium sulphite oxidation by copper. The authors suggested that these strong desensitising actions may be the cause of obscure troubles in emulsion making.

Mr. Sterry, in confirmation of his original observations, pointed to the fact that the chromate process was now in practical working for development of bromide papers. He referred to the difference in the condition of chromate in an acid pyro-developer, such as he suggested in 1899, containing one part of chromate in 50,000 or 500,000 parts of pyro solution as a developer of P.O.P. The chromate, no doubt, preserved the pyro. He had found that dipping a plate in chromate, followed immediately by development, caused a long curve in the under-exposed portion, and gave a higher "gamma infinity" than in ordinary development. Dipping with development after some time was examined by the speaker in a series of experiments, in the course of which a constant result was regularly reached. He was also able to use bromine and potassium permanganate satisfactorily between exposure and development. The latter was best used in 1 in 10,000 alkaline solution.

Mr. C. H. Bothamley, among other statements, said he agreed with Dr. Mees in the total undevelopability caused by potassium bichromate.

Dr. Mees replied, and a vote of thanks to him brought the meeting to a close.

**SOUTH LONDON PHOTOGRAPHIC SOCIETY.**—On Monday last Mr. W. L. F. Wastell, F.R.P.S., gave his lecture, "A Dive into Belgium." The lecturer's reputation as a humorist had preceded him, and his audience were not disappointed, being kept in a state of merriment by his gentle wit. At the same time, by a series of excellent slides, conveying a good insight into the scenery of canal and river, of street life and of the beautiful mediæval architecture of such historical old cities as Brussels, Antwerp, Ghent, Bruges, Louvain, etc., the lecturer travelled via the River Thames and across to Ostend, by which route he was enabled to obtain also some interesting pictures of river craft, and some fine sunset effects. The lecturer remarked that his pictures were all taken with a folding pocket camera, and fully demonstrated the usefulness of the hand camera to illustrate a lecture of this sort. At the next ordinary meeting of the Society on January 21, Mr. T. Manly will give his lecture and demonstration on Ozobrome.

**SOUTHAMPTON CAMERA CLUB.**—The members held their eleventh annual general meeting on the 7th inst., when there was a good attendance under the presidency of Mr. W. B. Hill. The Committee's report was a very cheerful document, showing progress all the way round, while the statement of accounts was most gratifying. On the exhibition account a profit was shown of over £15, and this, carried to the general account, made the balance for the year's working over £18 to the good, the sum at the bank to the club's credit being over £71. After the report and accounts had been adopted the members proceeded to elect officers, the President, Mr. W. B. Hill, and the Hon. Secretary, S. G. Kimber, both receiving musical honours on their re-election. Messrs. G. T. Vivian and A. Horsley Hinton were re-elected Vice-Presidents, and the names of Dr. Milner-White, LL.D., A. E. Henley, and F. G. Ryder, were also accepted for the same office. The Hon. Lanternist, Treasurer, and Reporter (Messrs. Vivian, Trigg, and Ryder) were again installed in office. C. D. Kay and the Hon. Secretary were appointed delegates to the R.P.S., and the Committee were elected as follows:—Messrs. Daw, Weaver, Cooper, Kay (W. R.), Baker, Essex (re-elected), Irish, Russell, Parson, and Smith (new members).

**WINDSOR PHOTOGRAPHIC SOCIETY.**—Councillor G. Bell Harrison opened the new headquarters of the Windsor Photographic Society

at 5, High Street, Cardiff, last week. Hitherto the society has been in residence at Quay Street, but the number of members having considerably increased, a wish was expressed for more convenient premises. The new rooms consist of a large lecture-hall, parlour, and a dark room, with every appliance and apparatus.

## Commercial & Legal Intelligence.

**ALLEGED CANVASSING FRAUDS.**—In support of a charge of false pretences preferred at Wigan, on January 2, against Robert Gibson, it was stated that the prisoner professed he was canvassing for orders for the enlargement of photographs, and collected 1s. a week from different persons, making all manner of excuses for the non-delivery of the enlargements promised. One woman had paid weekly from March to November. A remand was granted in order that several other cases might be brought against the accused.

### NEW COMPANIES.

**LILFORD AND CO., LTD.**—Capital £500, in £1 shares. Objects: To carry on the business of wholesale, retail, and manufacturing chemists, druggists, drysalts, oil and colour men, dealers in photographic, electrical, surgical, and scientific apparatus, etc. The first subscribers are: F. Porter, 18, Salford Street, Leicester, accountant; J. Heatherill, 16, Albion Street, Leicester, paper dealer; A. Hodgson, 57, Biddulph Street, Leicester, optician; C. Munton, 63, Basinghall Street, E.C., manufacturers' agent; T. May, 18, Halford Street, Leicester, accountant; H. T. Millman, 427, Welford Road, Leicester, accountant; and Mrs. B. J. May, The Lilacs, Knighton Rise, Leicester. No initial public issue. Re-registered without articles of association. Registered office, Bank Buildings, Gallowtree Gate, Leicester.

**J. SAVAGE AND CO., LTD.**—Capital £20,000, in £1 shares (10,000 preference). Objects: To adopt an agreement with J. W. Savage and G. S. Savage, and to carry on the business of druggists, drysalts, wine and spirit merchants, mineral-water manufacturers, perfumers, photographic outfitters, optical instrument makers, etc. The first subscribers are: A. Amber, Legrams House, Bradford, chemist and druggist; A. T. Bailes, 21, Ellercroft Road, Bradford, chemist and druggist; G. S. Savage, 8, St. Andrew's Villas, Bradford, chemist and druggist; H. Savage, 8, St. Andrew's Villas, Bradford, chemist and druggist; J. W. Savage, Ellercroft, Legrams Lane, Bradford, wholesale druggist; F. C. Savage, 309, Legrams Lane, Bradford, manager; and H. Raw, 21, Station Road, Clayton, Yorks, chemist and druggist. No initial public issue. The first directors are J. W. Savage and G. S. Savage. Qualification, 250 ordinary shares. Remuneration as fixed by the company. Registered office, 140, Listerhills Road, Bradford.

## News and Notes.

THE "Bromide Monthly," the familiar organ of the Rotary Photographic Co., appears with the New Year under the modified title, "Photo Notes and the Bromide Monthly." It is now printed on a paper which permits of half-tone illustration in the text, and will at the same time enlarge the scope of its articles as indicated in its new title. For some time past its programme of articles has ranged through all departments of photography, and its title with the suggestion that it was limited to bromide work has been a misnomer. The date of publication will now be the first of each month, and to induce interest in the new year the Rotary Company will send a copy post free on receipt of twopence in stamps.

THE Leicester and Leicestershire Photographic Society start the new year with a record membership of 192, no fewer than sixty-three of whom have been enrolled during the past twelve months, and the programme for the current session shows that those responsible for its production are very much awake to the desirability of up-to-date information. Mr. C. W. Leake has recently undertaken the duties of hon. sec., and communications should in future be addressed to him at 2a, Dulverton Road, Leicester.

THE Cripplegate Photographic Society's Exhibition will be held

from February 11 to 15, 1907. Entries close on January 28, 1907. The entry-forms are now ready, and can be had on application from F. O. Bates, hon. sec., 37, Beresford Road, Hornsey, N.

**PINATYPE.**—Messrs. Fuerst will give a demonstration at the Photographic Club on Wednesday next, January 16. The secretary of the Club asks us to say that any member of the Society of Colour Photographers, or any one interested in three-colour work, is welcome to attend the meeting, which is held at 19, Paternoster Square, E.C., at 8 p.m.

MR. LOUIS J. STEELE, who is to lecture on Alpine photography to the Royal Photographic Society next Tuesday, is electrical engineer

to the Portsmouth Dockyards, and, apart from his profession, has shown himself possessed of such accomplishments as painting, mountaineering, and photography. His record in Alpine climbing has made him a member of the Alpine Club and the Climbers' Club, and for many seasons he has made ascents of the Swiss and Italian Alps. The Hautes Pyrenées, and the wilds of the Canadian North-West are also familiar ground to Mr. Steele, who, despite his few years, has had many exciting experiences as a traveller, and has swollen the dividends of the plate-makers to the tune of 6,000 negatives. Mr. Steele, whose views on Alpine photography were communicated some months ago to the "Photographic News," and are summarised

MR. LOUIS J. STEELE.  
Photograph by F. J. Mortimer, F.R.P.S.

in the B.J. ALMANAC, is an adherent to the hand-camera, and rarely exposes an unbacked plate.

MR. F. T. CORKE, lately resigned from the managership of Messrs. Raphael Tuck's postcard department, has now established himself as the "Studio of Design," 2, 3, and 4, Cheapside, London, E.C., where inquiries as to any production and publication work, especially three-colour, may be addressed to him.

THE Photographic Convention.—A suggestion has been made that the 1908 meeting should be held in Edinburgh on the occasion of the proposed Scottish National Exhibition in Edinburgh in that year. The suggestion emanates from the guarantors of the Exhibition.

THE Houghton Smoker.—To see the large Crown Room at the Holborn Restaurant crowded by the members of the Ensign Athletic Club of Houghtons Ltd. was to obtain a forcible demonstration of the importance of the firm and of the cordial relations which exist between the principals and their staffs. Mr. Edgar Houghton occupied the chair, and with him were Mr. George Houghton (founder of the business), Mr. Charles Houghton, Mr. Smith (manager), Mr. P. G. R. Wright (advertisement manager), and Mr. A. S. Spratt and others representing the associated branches of Houghtons Ltd. The entertainment programme, arranged by Mr. Phil Payne, was admirable—we hope we may never have to listen to a worse one, but we are positive we shall—yet it is no disrespect to the artistes to say that not one of them was so enthusiastically received as the song, "Glorious Devon," sung by Mr. Austin Edwards, who had come from Warwick to attend the smoker. After more than £9 had been collected for the "Referee" children's dinner fund, an informal toast, "The Prosperity of 'Houghtons' and the Houghtons," was given by Mr. A. Horsley Hinton, to which Mr. George Houghton very simply and gracefully responded. The Houghton smoker was a function for mutual congratulations. Its numerical strength cast a flattering reflection on the magnitude of the High Holborn business, and its enthusiasm denoted a loyal staff. Long may it be an annual function.

## Correspondence.

*\*\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*\*\* We do not undertake responsibility for the opinions expressed by our correspondents.*

### THE MEASUREMENT OF BUILDINGS FROM PHOTOGRAPHS.

To the Editors.

Gentlemen,—I have to thank Mr. Harvey Collingridge for his very useful data regarding the variations in measurement of brick courses in different localities.

I must point out, however, that, as a matter of fact, no mention is made in my article ("B.J.," December 28) of brick or masonry courses being used for vertical measurement. I simply suggested that they could be employed to find the vanishing point and horizon line of a photograph, which is, of course, quite a different thing.—I beg to remain, etc., yours very truly,

A. LOCKETT.

88, Brook Street, Kennington, S.E.

January 4, 1907.

## Answers to Correspondents.

*\*\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

*\*\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*\*\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*

*\*\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

*"The Northern Photographic Company, Wesley Place, Blaydon-on-Tyne. Four Photographs of Lieut. T. Bates, 1st V.B.N.F."*

**THE POWDER PROCESS.**—I am an experienced commercial printer, disengaged, and have been promised a good engagement if I can work the dusting-on process. Should be glad if you could reply to this, and give me the whole process from the beginning, and a good and reliable formula. Should like, if you can, to reply in Friday's issue, as my living depends upon it.—**DUSTING ON.**

To give you full working details of the powder process would occupy far more space than can be afforded in this column. In "Burton's Photographic Printing," published by Marion and Co., several pages are devoted to the dusting-on process. We should recommend you to get this work. However, here is a good formula for the sensitive material, for this time of year: Honey, 3 drams; albumen, 3 drams, saturated solution of bichromate of ammonia, 5 drams; water, 1 pint. You must keep in mind that the whole process depends upon the hygroscopic state of the film, and less honey should be used in damp weather than dry. Of course, you know that in producing a positive picture a transparency, and not a negative, is necessary. The transparency should be a thin one.

**LENS FOR STUDIO CAMERA.**—I should be glad if you would kindly let me know if a half-plate lens; diameter of tube body  $4\frac{3}{4}$  in., and inside diameter of flange  $4\frac{3}{4}$  in., would be too large to be fitted to a  $8\frac{1}{2} \times 8\frac{1}{2}$  studio camera, or what size camera would be best for such a large diameter lens.—**J. T.**

A half-plate camera is naturally most suitable for a half-

plate lens, and one with square bellows and plain front with a sliding movement or loose panel should take the lens. A very rigid front is essential, as the lens must be heavy, but if you want any movements on the front, a whole-plate camera,  $8\frac{1}{2}$  in.  $\times 8\frac{1}{2}$  in., will be necessary. We cannot say if the lens will fit every pattern of whole-plate studio camera, but probably you can find one that it will fit. The focal length will be too short for whole-plates, but you can use half-plates in carriers.

**VARIOUS.**—The Editor of the BRITISH JOURNAL OF PHOTOGRAPHY would oblige by stating, in Answers to Correspondents column, where a work on "Line" can be obtained. 2. Also where imitation jewellery, as seen on enclosed card, may be obtained.

### LINE.

1. We are not quite sure of your meaning, but apparently "A Handbook of Illustration," by A. Horsley Hinton (Dawbarn and Ward, ls.). 2. From Reinemann and Co., New Zealand Avenue, Barbican, E.C.

**SOLUBILITY.**—In the table in your "Almanac" and the "hot water" column, the word "decompose" appears opposite one or two chemicals. 1. Does this mean that if that chemical is dissolved in hot water its power or virtue is destroyed, and that that particular chemical should be dissolved in cold water always? 2. Is there any table in the Annual from which I can get the amount of a given chemical which, if dissolved in a given amount of water, will make what is called a "saturated solution"? I often want to make a saturated solution, and it would be most useful to have such a table. Of course, the table of solubilities would do if the figures there mean that the given quantity of water will dissolve the given quantity of chemical and no more.—**W. ISON.**

1. The substance is altered wholly or partially, and cold water should be used. 2. All the figures are for saturated solutions. Thus, 50 parts of lead nitrate (p. 1,106) in 100 parts of water make a saturated solution.

**CELLULOID.**—I find a difficulty in procuring exactly what I want, and should be glad if you could give an address where such a thing is obtainable, viz., celluloid (very thin) coated with a slow emulsion to make transparencies on, and without the gelatine coating on the celluloid side.—**TEETOTALER.**

Try the Lumière N.A. Co., 4, Bloomsbury Street, London, W.C. The only marketable form of the material is that used for cinematograph work.

**GASLIGHT POSTCARDS.**—I shall be much obliged if you can give me the quickest process to print gaslight postcards. Can they be printed while the negative is wet? Also, can they be dried with methylated spirits. If so, which is the best make for this process?—**B. POULTER.**

The quickest way would be to use one of the special printing machines for the purpose, such as the Reynaud, the Hana, or the Sickle, particulars of which you will find in the "Almanac." We should not advise you to take more than one or two prints from a wet negative, as you are sure to get it damaged in making a number. The gaslight print may be dried with spirit, but the surface is not improved by the process; the usual way is to blot the prints off on a hard blotting-paper or muslin and dry them in a place where there is a current of warm air.

**F. K.**—We should certainly advise 1 in preference to 2, in view of constant use.

**AMIDOL.**—I have been troubled with amidol stain on my finger nails ever since I have done black and white printing, and should be much obliged if you could tell me anything that would remove same.—**AMIDOL.**

By rubbing a little crystal of ammonium persulphate on the fingers.

**A PATENT QUESTION.**—Four practical photo printers have invented a most simple but efficient time-saving attachment for printing frames. They have in confidence submitted same to a practical manufacturing wholesaler, who is greatly taken up with the idea, and whose only reason for not advising its protection is, so far, that it is so simple that when on sale every amateur or other who sees it will simply say "Splendid idea," and not buy, but go home and in a couple of minutes make the alteration to his own printing frame—as we understand, legally there is nothing to prevent him so doing. In consequence, we should be

greatly obliged if you would inform us what the law would be under the circumstances below: Taking it that anyone can copy and use a patent article for their own use, would this mean that any firm could do so for their own use? A firm of trade printers could make the alterations to say 500 frames, and thus save yearly, perhaps, £200 in wages. The point is, as they would not offer the improved frame for sale, would they be in any way liable for infringement under the patent laws?—R. BELL.

It is illegal to make a patented article or use a patented process. This applies to both firms and individuals.

**RETOUCHING (E. E. L.).**—A considerable advance upon the last specimens you sent. Soft and natural work, but the modelling is open to improvement. The nose should be made to stand out in better contrast to the small cheek, the face line more clearly defined, and all the high lights strengthened. Impossible to fix salary. What we consider you are worth does not concern an employer of retouchers. Make the best terms you can.

**ARC LIGHT.**—My studio is a sidelight only from a large window facing south, no top light being available owing to rooms over. I get good results for a bust, but figures standing full length are very dark on shadow side. Although I use powerful reflectors, and the room is of a very light colour, it is impossible to tip the cheek on shadow side, which gives roundness unless turned to the light. Would it be an improvement if I employed an arc overhead such as the Jandus, carefully diffused through curtains, etc., so as to use the daylight and arc together? I possess a Boardman open arc, but I think I should need one of the enclosed type (movable) on an overhead wire. Should it be much in front of sitter so as to illuminate bottom portion as well? Your valued opinion would be of great help to me.—B. O. O.

If you read the article on p. 1,023 of the issue of this journal of December 28 last, and that on pp. 716-7-8 of the "Almanac" for the current year, you will probably see a way out of your difficulty. The article in the "Journal" deals with the subject more fully than can be done in this column, and applies especially to such cases as yours.

**PRICE OF LENS.**—I have just bought a lens at a dealer's (second-hand), and it is marked Richter's universal rapid aplanat, No. 3. Could you tell me what price it is listed at; if not, whether it is by a good firm? Thanking you for the trouble I am giving you in the matter.—A. Y.

We are sorry we cannot give the desired information, as we do not possess a price-list of the maker whose name the lens bears. Personally we have not tested any of these lenses, so are unable to give any opinion on their merits. You can easily test its quality by taking one or two pictures with it, using a large aperture.

**POSTCARD STATIONERY.**—Would you kindly give me the names of suppliers of (1) picture postcard albums, wholesale; (2) revolving and other holders for displaying picture postcards?—HEATHER.

(1) Raphael Tuck, Moorfields, London, E.C. (2) St. Paul's Studio of Design, 2, 3, and 4, Cheapside, London, E.C.

**GEO. HRST.**—In almost all cases it is methyl violet.

**FINISHER.**—We should advise you to obtain a square camera bellows camera or one with not too small a front. It is not so easy to combine all the requirements in one instrument, but the chief point is to have it rigid and firm, and of sufficient extension. This must be at least double the focus of any lens that you use.

**LANTERN.**—Yes, there is no doubt that the heat from the lantern melted the film, which could not have been properly dried. We should advise you to use the fixing bath given on p. 727 of September 14, 1906, or p. 759 of the Almanac. After this no heat will affect the film.

**COLOURING P.O.P.**—Will you in your next issue kindly inform me how I may colour P.O.P. prints? I have read somewhere that by pasting print on glass, then scrape or glass-paper the back of print until only the film remains. I believe wax is used in the process, then the print is coloured with water-colours, I believe, on the back of print. I have lost the book in which I read about it.—WM. G. LOWRY.

The method referred to is no doubt that known as *crystoleum*, in which the print is affixed face down to glass, the paper removed by friction and scraping, and then the colours applied. It is almost impossible to satisfactorily apply this process to P.O.P., as this is coated on a gelatine and baryta surface paper, which is absolutely opaque and difficult to remove. The old albumenised paper is the best for this purpose. Full instructions can be obtained from Alston and Co., New Bond Street, W.

**C. D. V.**—The picture is obviously either a collodion or gelatine positive, toned with uranium, and backed up with gold leaf or Dutch metal, the latter most probably. We know of no firm who now do this, but you can see from the above how easy it would be for you to do it yourself.

**F.R.P.S.**—Would you be good enough to inform me (1) if the annual subscription of £1 1s. to the Royal Photographic Society authorises the photographer to use the letters M.R.P.S. after his name? (2) How is the F.R.P.S. obtained?—ANXIOUS.

1. No, there is no such title. 2. Applications from members for the fellowship are considered twice a year by a committee which recommends or does not recommend election of the applicants. The final election is by the Council. You had better write the Secretary of the Society, Mr. J. McIntosh, 66, Russell Square, W.C.

**COPPER TONING P.O.P., ETC.**—1. Formula for a reliable copper toning bath for P.O.P. Also is copper permanent? 2. Do you know of a process which will give the following: Prints from tracing negatives which can be done by magnesium; the lines must be black, and the paper on which the print is done must be in a condition to take water-colours. I have seen advertisements of printing by what they called the West process, in which they claim that the lines are printed in Indian ink. Do you know of this process?—ARTHUR J. PRENTICE.

1. Whilst it is possible to apply copper toning to P.O.P., results obtained are extremely unsatisfactory, and not worth bothering about. 2. A process of this kind is worked by Messrs. B. J. Hall and Co., 39, Victoria Street, London, S.W., and Messrs. Norton and Gregory, Westminster Palace Gardens, London, S.W., but neither supplies the materials.

**REGIMENTAL MOUNTS.**—In reply to a recent correspondent, Mr. Hamilton Smith writes from Devizes, saying that "regimental mounts" may be obtained from Gale and Polden, Aldershot.

**STATE CINEMATOGRAPH FILMS.**—Animated records depicting Parisian state ceremonies, great gatherings of public and national interest, festivals, manoeuvres, and the like, are to be handed down for the use of future generations of students of French national life and customs. The municipality of Paris has decided to establish a bureau for the sole purpose of acquiring and preserving such films, thus recognising the value of the cinematograph as an educational factor. These present day business methods, and the state functions of our generation, will prove of inestimable value in the future, but no official movement has hitherto been made to secure the subjects. For electioneering purposes, too, animated pictures are proving not only of present use, but will serve as permanent records of the methods of our time, and thus be more serviceable than any still life pictures or verbal and statistical descriptions.

**\* \* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The first of a series of chapters on the working up and colouring prints and enlargements with the aerograph appears on page 40.

The Progress Medal of the Royal Photographic Society has been awarded to Mr. E. Sanger Shepherd for his researches in three-colour photography. (P. 52.)

We regret to record the death of Mr. Sebastian Davis. (P. 46.)

Mr. F. C. Tilney, in some notes on the portraits by American professional photographers now being shown at the B.J. offices, comments on the freedom from excessive retouching and the command of lighting and mounting which many of the examples show. (P. 41.)

An American professional speaks of the favour into which carbon printing has lately come among professionals in the States. (P. 44.)

The patented Pietzner method of colouring photographs by means of a stripping film is the subject of an article on page 42.

Mr. Herbert E. Ives has published details of a method permitting the duplication of Lippmann colour photographs. (P. 38.)

A man, who has been practising the most impudent canvassing ruses in the North of England has been sentenced to jail for two months. (P. 46.)

An ambitious scheme for using micro-photographic reproductions of books and documents has been advanced by the Brussels Institut Bibliographique. (P. 39.)

Roller-blind shutters and other shutter mechanism, invisible printing and panoramic cameras are among the patents of the week. (P. 48.)

Uniformity of formulæ for developers of plates and papers is a point put forward by Mr. A. Gascoigne. (P. 43.)

A German writer has published instructions for the making of artificial negatives. The directions should equally serve for the production of diagram lantern slides. (P. 45.)

## Copyright in America.

### EX CATHEDRA.

Photographers in the United States are justly indignant at the efforts being made through Congress to deprive them of the rights of reproduction of their photographs which it is proposed to grant them under a revision of the copyright law of the States. As the Bill recently stood before the American legislature it did give the photographer some protection against those who, under the existing conditions, can take what is not theirs with impunity. An amendment, obviously emanating from the newspaper proprietors, has been put forward to the effect that "Provided, however, that the reproduction of a photograph in any newspaper by the process known as stereotyping shall not be construed as the infringement of the copyright of such photograph." It is difficult to suppose that a barefaced proposition such as this can carry any weight in the alteration of a measure which at present is reasonably equitable, but only a slight acquaintance with American politics is necessary to recall instances of similar travesties of justice having proved successful. We hope, therefore, that photographers throughout the States will respond to the call of Mr. B. J. Falk, the president of the Photographers' Copyright League, by such an outcry as shall compel the Government to place photographers on the same footing as other illustrators in the matter of copyright in their works.

## Pictorial Photography in London.

On Monday, January 28, at the Galleries of the New English Art Club, 67A, New Bond Street, an exhibition will open of photographs by the following:—

J. Craig Annan.  
Alvin Langdon Coburn.  
F. Holland Day.  
Robert Demachy.

Gertrude Kasebier.  
A. de Meyer.  
C. Puyo.

The exhibition, which will remain open for a fortnight, will afford an opportunity of seeing again works of the pictorial school which have been admired at previous exhibitions, but it will be chiefly remarkable for bringing again before the public the photography of Mr. Holland Day, whose mystic productions attracted a good deal of attention a few years ago, and obtained, we are glad to remember, some candid outspoken criticism. The arrangements as to organisation and hanging of the forthcoming exhibition have been in the hands of Mr. A. L. Coburn, to whom our congratulations are offered in advance on providing the opportunity for an inspection, side by side, of the work of MM. Demachy and Puyo, three notable American photographers, and one Scotsman in the person of Mr. Craig Annan.

## Three-colour Lippmann Photography.

Apart from the long exposures necessitated by the slowness of the emulsion, the fact which has stood in the way of the more general use of the Lippmann interferential pro-

cess of colour photography is that it has so far been impossible to reproduce the results. A hope of the realisation of this was held out by Professor Lippmann in a paper published in the *BRITISH JOURNAL OF PHOTOGRAPHY* for June 30, 1905, p. 505, in which it was pointed out that brilliant complementary colours could be seen from the back of the film when bichromated gelatine bearing an interference photograph had been saturated with silver iodide; but beyond that stage no advance has been made. Now Mr. Herbert E. Ives has published a method by means of which it is possible to duplicate interferential photographs. The method adopted is extremely simple and is based on the use of three-colour records or transparencies projected by means of an enlarging lantern and sunlight, with the aid of a heliostat, on to a grainless emulsion plate, in contact with which was a grating having the opaque spaces twice the width of the transparent. When an exposure has been made with the one-colour record illuminated by the correct coloured light, the grating is shifted so as to cover the exposed line and uncover another unexposed line, and the transparency is changed and also the light. These operations are then repeated for the third colour record. It will be seen that the process may be said to be a combination of the three-colour method, with the shifting grating (as described by Mr. Ives for his diffraction process in our issue for August 3, 1906) and the Lippmann process. To quote the author's words, the results "are not, of course, colour pictures taken directly in the camera, the ideal for which we aim, but they are faithful colour pictures, produced entirely by photographic means; they are held in the hand to observe, and may be duplicated indefinitely." The full text of the paper will appear in our next "Colour Photography" supplement.

\* \* \*

#### Bogus Impressionism.

In his Royal Academy lecture on "The Hour," Professor Herkomer made some timely and much-needed comments on the bogus "Impressionism" that so often poses as "Art." The Professor's remarks were aimed chiefly at a certain modern French circle of so-called artists, but as the influence of the offenders is by no means confined to France, and has certainly contaminated photography to some extent, this particular Royal Academy lecture deserves a wide circulation. Professor Herkomer referred to the works of Turner and Holman Hunt as examples of true impressionism, for, widely as these two painters differed in their views, "both painted their impressions." He denied that the modern decadent school had any right to the name of "Impressionists," and suggested "Imperfectionists" or "Idiotists" as more truly expressive designations, for, "It's the badness of the work that knocks one over," remarked the Professor as he dramatically unveiled some shining examples of the "Modern School." He told a story that illustrates most aptly the characteristic line of defence adopted by the perpetrators of these fraudulent productions that masquerade as pictures. He described one of the "masterpieces of the school" shown him by a disciple in Berlin. He asked the disciple if he thought the picture was a good composition. "No. That was not its aim." Did he think it well drawn. "No. That, again, was not its aim." Nor was colour; and of its real aim the lecturer was still ignorant. There is always a comic side to such travesties of Art, some of which, as is well known, have been deliberately produced for the simple purpose of playing a practical joke on the critics.

\* \* \*

#### The Decay of Illustration.

A writer in "The Academy" deplores the degeneration of "black-and-white" artists. In another column we print an extract from the article, by which it will be seen that the

imitation of a photograph is held to be the *ignis fatuus* which has lured the poor foolish artist to destruction. According to the dicta of many authorities, however, this must be a veritable turning of the tables upon the artist. For our own part we do not agree with our contemporary, for we fail to see that the dozen or so of illustrators who drew for "Once a Week" and "Good Words" in the famous sixties cannot be matched to-day. The real point is, we think, that there are now perhaps a hundred times as many doing the same thing less well, to whom the door has been opened by cheapness in reproduction. Forty years ago the cost of making blocks was about twenty times as great as it is to-day, and it would never have paid editors then to have spent from five to ten pounds upon engraving such a drawing as the cheap magazine can get to-day for ten shillings. There are just about as many good artists as ever there were; but there are also hosts of inferior ones nurturing upon art-editors who ask for cheap drawings; and the name of such editors is legion

\* \* \*

#### Stereoscopic Lantern Slides.

A correspondent in "Nature" (December 27, 1906) suggests what he considers to be two very easy ways of showing stereoscopic slides to a large audience. In the first place a slide showing a pair of stereoscopic pictures is prepared, and the two pictures are projected side by side on the lantern screen. Each member of the audience is then supplied with a form of stereoscope through which the pictures are to be observed, one form suggested being two mirrors apparently arranged somewhat in the manner of Mr. Theodore Brown's "stereoscopic transmitter," while the other form is a simple prism placed in front of one eye. There is nothing new in these suggestions, and there are many other ways in which the same purpose can be fulfilled, but from our own experience with various forms of stereoscopes we are inclined to think that very few members of the audience would master the use of such out-of-the-way contrivances. In the ordinary prismatic stereoscope everything is made easy for the observer, and, provided the instrument is properly adjusted and the vision is not very abnormal, almost anyone can quite readily see the stereoscopic relief. This instrument is, however, the only one that is really easy to use from the beginning. A non-prismatic or lenticular stereoscope of similar form is not so quickly mastered, neither is a Wheatstone reflecting stereoscope. With all these instruments the pictures observed occupy a fixed position and the whole apparatus can be so arranged that with a little practice the effect is readily secured. But when the optical portion of the apparatus is quite disconnected from the prints one has not only to adjust the mirrors or prism, or whatever it may be, but also to secure a right direction, and this is not always easy even when one is fairly expert. What we may call "one-eyed" stereoscopes, such as the prism suggested, are very troublesome to use. We are much inclined to think that the double mirror arrangement suggested for use as a stereoscope would be quite as troublesome as the one-eyed arrangement, and just as ineffective in the unpractised hands of a mixed audience.

\* \* \*

#### One-eyed Stereoscopes.

It is very desirable that instruments such as these should be used with caution, for, from the nature of their construction, they generally put a very undesirable strain on the eye. This may not be the case when a distant lantern projection is observed, but it undoubtedly is so when an ordinary stereoscopic slide is studied at close quarters. The optical construction, whether it be an arrangement of mirrors or a simple prism, lengthens the path of the rays from the object to the eye, hence the eyes are focussed on different

distances, and their accommodation varies. This is an altogether unnatural state of things, and the strain, which is of an injurious kind, is very soon felt. In a properly adjusted lenticular binocular stereoscope of any ordinary pattern there is no strain whatever to injure normal eyes, and the effect required to combine the pictures with non-lenticular binocular arrangements, or without any instrument at all, does not involve any strain that is likely to work mischief. The eyes work in unison in these cases, but the independent accommodation required with the monocular instrument is just as apt to work mischief as the use of the familiar "monocle," which no one can wear except at the cost of damaged eyesight.

#### MICRO-PHOTOGRAPHS AS DOCUMENTARY RECORDS.

In the report of the congress of photographic record at Marseilles, which appeared in our issue of November 23, was a reference to a scheme proposed by a M. Robert Goldschmidt, of the Institut de Bibliographie, of Brussels, which was stated to be receiving the consideration of the Congress. M. Goldschmidt's paper has since been published by the Institut under the title "*Sur une Forme nouvelle de Livre*" ("On a new form of book"), and turns out to be a most ambitious and comprehensive scheme of applying photography to library and bibliographical purposes. According to M. Goldschmidt the present system of storing the actual volumes published for general reading is too heavily weighted with drawbacks to answer much longer the purposes of directors of large libraries. In considering the formation of a great international centre of bibliography, the obstacles in the way of collecting original books, periodicals, and manuscripts, not to say of finding room for their storage, appear so enormous as to lead the Brussels Institut to formulate a plan which is advanced by it as satisfying the following conditions laid down in reference to the constitution of an ideal library of reference. The desiderata in a document to be consulted at intervals in an immense library are:—

- Small weight and volume.
- Uniform size.
- Absolute permanency.
- Low cost.
- Facility of storage.
- Ready accessibility.
- Facility of duplication and of multiplication.

The realisation of these conditions are to be found, we are told, in the micro-photographic reproduction of the printed volumes and journals. The tiny copies are to be made on a flexible film the rolls of which are susceptible of storage and are equally readily available for consultation by insertion in a projection lantern or lantern microscope. This idea, as the brochure points out, is not an entirely novel one, for it was suggested in 1865 by Wharton Simpson, and, indeed, six years previously, at a meeting of the Manchester Photographic Society, some photo-micrographs were exhibited, of which one was a copy of two pages of "Quekett's Treatise on the Microscope" reduced to the superficial area of one-sixteen hundredth of an inch. It included 3,631 letters, every one of which was as perfectly sharp and legible as in the original printing. But a scheme of such magnitude as that of the Brussels Institut has probably not been advanced, and we are doubtful if the suggestions of M. Goldschmidt are backed up by practical trials of the process in the application which is suggested for it. For the requirements of the micro-photographic book are very exacting ones. According to the brochure before us the size of the standard section of film which is to contain these bibliographical

records is to be that of the international postage stamp, or 1 by  $\frac{3}{4}$  inch, and in this area it is proposed to reproduce 72 pages of a printed book, with space between the pages to permit of them being separately examined. The writer appears to anticipate some little difficulty in obtaining images of sufficient fineness of grain to permit of legible projections of these minute negatives, or copies, and he mentions casually that the present celluloid film, from its inflammability, would not be adapted to the purpose, but that a non-inflammable film is merely a problem for the technical chemist. He is right. It is.

But unless we are mistaken there is another equally formidable objection to the successful employment of the micro-photographic method, and this will be apparent on considering the problem which confronts the photographer who is asked to prepare a film of postage stamp size containing the copies of no less than 72 printed pages. Assuming that these latter are the moderate size of 9 by 5 inches, a common size of type space in scientific works, and that they are arranged in six rows of twelve pages each across the length of the film, a simple arithmetical calculation will show that the length of a single printed line will be less than one-seventieth of an inch, even when no allowance is made for space between the pages. An average number of letters in a line of type occurring in such a page is something over seventy, so that the breadth of a letter in the micro-photograph is about one five-thousandth of an inch. Such a minute degree of definition calls for the very finest grain in the plate. The supporters of the scheme appear to have recognised that commercial dry plates will avail them nothing in their work, but they do not say how they will obtain the necessary fineness in their sensitive material. We very much doubt the ability of anyone to get it except under the most favourable conditions—conditions which we believe could not be fulfilled with the certainty and regularity which such work as the reproduction of pages to be read by students of necessity requires. Mr. George Shadbolt, many years ago, exhibited some of the earliest micro-photographs to be made by the wet-collodion process, and in the *BRITISH JOURNAL OF PHOTOGRAPHY* for 1859 (p.104) gives a description of his method of working. He mentions there the necessity of securing a structureless collodion, and what was true at that time is to all intents and purposes true to-day of the collodion process. The usual iron developer will not give the fineness of deposit which is obtainable with pyrogallie acid. With this latter reagent the image amounts to something very like a stain instead of a granular deposit, and in conjunction with a neutral sensitising bath the best conditions are provided for the attainment of the very critical definition which the proposed record work calls for from the photographer.

**GASLIGHT Postcards.**—A correspondent writes: Perhaps your correspondent, "B. Poulter," in your issue of January 11, may not be aware that "Tula" postcards, manufactured by the Bayer Company, may be treated with hot water, and dried by heat in a few minutes.

**THE Cinematograph at the Alhambra.**—In appreciation of the paramount excellence of the "Urbanora" animated picture exhibit, and in order to afford still greater facilities to the expert operators of the Urban Company, the management of the Alhambra has had constructed a new and spacious cinematograph chamber with a unique electrical equipment. It is (as, indeed, is the entire theatre, and every inch of scenery and drapery within it) absolutely fireproof, and, unlike its predecessor, is out of the view of the public, and merged in the scheme of rich Moorish decoration which distinguishes the celebrated place of entertainment. The apartment was used for the first time on Monday evening last, when some very beautiful and realistic scenes of the Atlantic Ocean were added to a programme already replete with variety.

## WORKING - UP AND COLOURING WITH THE AEROGRAPH.

The following first number of a series of articles on this subject deals with the general principles of the application of colour to photographic enlargements and prints by the means of an air-spray of colour. The succeeding instalments will treat of the care and manipulation of the instrument, the choice of the best colours, the working-up of different types of subjects, vignettes, etc., and the special methods of portrait colouring.

It is the purpose of the writer to make these papers on "aerograph work" as practical as possible, avoiding theories and debatable points, and dealing with technicalities. There may be references to the materials, such as colours, supplied from various sources; the artist, the beginner especially, wants to know definitely about these things, so it may be necessary to mention the names of makers, and although one may be recommended, it will not follow that others are not as good, but only that they have not come within the experience of the writer. We shall deal with the character of the enlargement, the colours to be employed, the treatment of backgrounds, and details of pictures, etc. But we think that our first chapter should be one on the handling and the care of the instrument and hints for beginners.

### The Difference Between Aerograph and Brush Work.

There are many artists who have acquired the technique for finishing photographs with a brush who will be interested to learn more about "aerograph" technique, as the two differ very considerably—almost as widely as oil painting and water-colour drawing. The difference is inherent in the tools, if I may call them such: a brush naturally makes a hard definite spot, or line of colour, whereas the "aerograph" makes soft lines and easily-graduated tints. This means in practice that brush work must be applied with much nicety, and great care exercised to obtain softness, whereas with the "aerograph" care must be exercised to keep the work as sharp and definite as possible. Perhaps in practice the best results are obtained with a judicious combination of the two methods; but the writer is of the opinion that at the present time only a few artists have given sufficient attention to the technique of the "aerograph" to thoroughly master the possibilities of the instrument. It is quite natural that artists who have spent several years acquiring the skill to use a brush, should be slow in changing their method of work, and if they only use the "aerograph" occasionally for broad washes, they might work many years with the instrument and never understand its possibilities or be said to have properly acquired the technique of the "aerograph." It will probably be many years before the art of the "aerograph" is properly understood, as it will be necessary for artists to be developed by the use of the instrument, as they have been with brushes, to inform us of its capabilities and its limitations. At the present time it is serving as an aid to artists—and principally trade art; but to come more directly to our subject,

### The Principle of Aerograph Work.

The colour leaves the point of the "aerograph" in a gradually-expanding spray, or, in other words, the colour which is in the air forms a cone with its base on the paper and its apex at the point of the instrument. It is therefore obvious that the further from the surface the instrument is held the broader will be the surface covered. This, with the fact that the amount of colour delivered determines the depth of the tint or line, is, broadly speaking, the whole theory of its application, but there are many points of consideration which must be understood to make practical application of the method. For instance, the "aerograph" does not make a flat tint except as it is applied in overlapping strokes; we can best explain this by a diagram. Let Fig. 1 represent, diagrammatically, in cross section, the quantity

of colour delivered by a single stroke of the "aerograph"; the colour is deeper in the centre and decreases gradually to each edge of the stroke. To make a flat tint it is necessary to overlap a number of these strokes, as in Fig. 2,

Fig. 1.

Fig. 2.

which makes for all practical purposes an even tint. It is obvious from this that the artist should take strokes with the "aerograph," as he does with the brush, and the strokes should be parallel and overlap (3-B-B) (3-B-B-B).

It seems hardly necessary to say that if an attempt is made to get an even tint with a circular movement, as one could do with a stump, the result would be failure, as where lines crossed the colour would be deeper, and a lumpy (we cannot call it a cloudy) effect would be produced.

### To Begin: How to Make Strokes.

Everyone who has used a brush for washes of colour knows that skill and long practice are required in the art of bringing the brush in contact with the paper, and in removing it at the end of the stroke to avoid irregularities of line and superabundance of colour. With the "aerograph" the starting and stopping point of the line or stroke are critical points. The hand carrying the instrument must be in motion at the time when the finger button is pressed to start the flow of the colour, and must continue its movement until after the flow of colour is stopped at the end of the line, otherwise there will be surplus colour at the ends of the line or stroke. Take strokes with the instrument and stop the flow of colour at the end of each stroke. Do not try to work keeping the colour on and dodge from one part to another.

Where a tint requires a sharply defined edge it is necessary to work with a line along the edge, gradually getting further from the surface of the paper as one gets away from the edge of the tint.

In certain classes of work, as in drawings of machinery, etc., to be reproduced by process engraving, the sharpest definition is required; tracing-paper masks may then be used to secure sharpness, but for portrait subjects we should not advise masking. Additional sharpness may, however, be obtained with the eraser. But we shall have more to say about erasers in a later chapter.

To keep the point of the "aerograph" near to the paper helps to keep the work sharp and clean.

### Tints, Shadings, Lines.

Having learned to make strokes with the "aerograph," in making tints and shadings, it is important that the strokes should follow the contour of the portion of the picture to be shaded—i.e., if shading the curve of the cheek in a portrait, the strokes should always follow the contour of the cheek.

And now a few words as to making lines. It is, of course, obvious that for sharp lines the point of the instrument should be very close to the paper—the point of the instrument may even rest on the paper if held at a slight angle. For very fine work the little guard may be removed from the point of the instru-

ment, only great care must be taken not to bend the point of the needle, which would then be exposed.

It is absolutely impossible to do very small drawings unless the instrument is set for a fine line by means of the knurled band—the instructions sent with the outfit explain the operation of this regulator for the line, so we will not go into it here, only to say that this band must be changed slightly for different colours, as all colours do not flow with the same freedom.

The knurled band should be set for the minimum amount of colour or the finest lines that are required for the work in hand. One can easily do small details of a drawing, if certain that when the finger lever is pressed (keeping it forward) one is only going to get a definite small quantity of colour, but if you have to press the lever and then gradually pull it back until the colour comes, you are working at an unnecessary tension and with a large degree of uncertainty, and the colour is likely

to come too suddenly and spoil the work. **DO NOT TRY TO DO FINE LINES WITHOUT HAVING THE INSTRUMENT SET FOR A FINE LINE.**

And while on the subject of lines we should like to say that many workers with the "aerograph" are content to use the instrument for tints only, and do not try to make it useful for lines.

There is not much doubt that while there is a great saving of time by laying tints with the "aerograph," there is still greater advantage in using the instrument for lines; the technique is much more difficult to learn, but, once acquired, the artist has lines of all the varying degrees of softness which no other artist-tool can give.

In the next article, after instruction in the care of the "aerograph," we shall proceed to the use of the eraser, the selection of the other few accessories, and the choice of colours.

## PORTRAITS BY AMERICAN PHOTOGRAPHERS.

BETWEEN the best photographic portraiture of America and the best of other countries there has always been a slight but sufficiently distinguishing difference. As long ago as a quarter of a century I remember being struck by the stylish look of certain portraits of actors that were displayed in French's windows in the Strand. These were by Sarony, and I have a distinct remembrance that the celebrities they portrayed seemed to be more dignified and irresistible people than our own notables, as rendered by the leading London photographers. The American work was usually larger, and mounted on heavier boards, of "panel," and other shapes new to me. The work was, as a rule, of richer colour; the poses of the sitters more arresting; and the general finish smarter. Perhaps, all this was a false impression, the outcome of inexperience in these things; but whether it were so or not, one fact remarkable about the matter is, that American professional work to-day gives me exactly the same impression. It seems to be in the van of progress. New departures, quaint developments, and all those slight changes which come about, not because there is any real need for them, but because they excite interest and cupidity in the customer—all this freshness of style seems to spring into being on American soil.

At the "little gallery," in the premises of "The British Journal of Photography," there is now arranged a show of about eighty works by American professional photographers. A more instructive and inspiring exhibition could hardly, I should think, be placed before any operator who is anxious to pick up suggestions as to ways and means.

One of the first things that will strike such a visitor is the passing away of that egg-shell texture of flesh, resulting from laborious and ill-directed retouching. The faces shown here, even those that have been exhaustively retouched, are not at all the porcelain masks, at which the amateur delights to sneer. They are fleshy, even if they are smooth and wartless. And in this exhibition, wrinkles and other signs of age appear to be capital in the photographer's hands, and the interest derived from it is certainly very great.

W. M. Hollinger, of New York, shows a lady whose face is all wrinkles, and whose hands, holding her spectacles so naturally in her lap, tell the same tale of a life spent in good works, as does the face. Beneath this excellent piece of character hangs another, which though entirely different in subject, resembles it in the matter of a suggested smile, or rather a smile held back, but anxious to be let loose all over

the face. The charm of such an expression can be imagined, when, as in these cases, it is the outcome of the sitter's own feelings, and not a property affair displayed at the operator's suggestion. Mr. Hollinger has evidently the knack of interesting and amusing his sitters, and making them feel the fun of the thing. These two sitters have entirely lost sight of the awful, haunting doubt of ladies in these circumstances—"I wonder whether I'm looking all right." The latter subject, together with the other works here by Mr. Hollinger, instances his fine sense of colour-values. The handsome full-face, though surrounded by darkness of tone, is by no means bright. The brightness is all left to a scarf or necktie, and the face is without conventional high-lighting. It keeps its place and retains its importance by other means than being the brightest thing in the picture. Consequently, it appears to have the proper colour-tone of flesh, as compared with the tone of a white scarf. This is one of Mr. Hollinger's methods, judging by its employment in four other works, No. 4 of which, by the way, all but speaks.

A young man's face, by Browne, seems to me to suffer by a too concentrated lighting, which culminates upon the nose; a system that would appear impossible unless a candle were held close to that organ.

Elias Goldensky, of Philadelphia, achieves lovely effects in low tones, without any loss of the charm of brilliance. No one should miss the delightful profile of a girl with her head bent. All the face is in a clean, deep tone and the light upon the shoulder is but the merest bit lighter than the background. The mounting, in ochre-tinted papers, is entirely harmonious with the print. A full-face is lit from beneath, the chin receiving the only high light, and the background having a luminous treatment that makes a picture of a head thus trickily lighted. Mr. Goldensky evidently gives a deal of thought to his schemes of light and effect. He "patterns" his subjects, and thus gives them a pictorial value that is an incalculable asset to a mere likeness, however good that may be upon its own merits. In his mounting, the tints almost invariably match the colours of the print.

An irresistible little girl in a print dress is signed Baldwin. Her pose is new and pretty; but what I should like to draw attention to particularly is the admirably convincing differences in the textures of the print frock on the one hand, and of the hair and flesh on the other. Those differences are of the utmost value in such a subject as this.

### A. Photographer of Children.

One screen is entirely devoted to the works of E. B. Core (New York), who specialises in children. It appears to be his object always to get a pictorial idea into these youthful portraits. In one, for example, half-a-dozen children are playing at school. In two others, a young baby is introduced as motive. The infant is held in the arms of a nurse, who holds it down to a child that reaches up to take it; or the baby forms an object of interest to its mother and grandmother who bend over it dotingly as they sit upon a settle. Perhaps, the finest of the baby pictures is a circular print of a mother and child; the former quite taken up with the latter's behaviour, and oblivious of herself; the baby on the utmost stretch of expectancy and wonderment as to the "little bird," or other base subterfuge by which the camera man has secured its lively expression. Another print shows five separate portraits of a child's head, à la Reynolds's so-called angels' heads. It is an idea, certainly, but one that would soon pall by repetition.

### J. S. Strauss and Pirie Macdonald.

Another idea is seen in the costume or historical exploits of Strauss (St. Louis), who selects with admirable cleverness his types of sitter, and disposes them in costume and pose recalling certain classes of painting. Thus one looks for all the world like a Holbein, another like an Italian painting of the great periods. Amongst them is an actual imitation of a portrait of Napoleon, and the likeness is remarkably good. Herr Dührkoop, from whom, by the way, this collection comes *en bloc*, is photographed as a Venetian Doge. Naturally enough, all this sort of manœuvring involves a deal of hand-work, and in my humble opinion, it is just there where these clever things fall short. The purely photographic part, and the carrying out of the idea are commendable; but the drawing and painting that have been added are not convincing. Some of the hands "give the show away," if I may be excused such slang. Mr. Strauss also shows some delightful child portraits, the most moving of which, is perhaps, the one that is caressing its mother's face. All the work in this section is forcible and rich.

Pirie Macdonald ("The photographer of men," New York) may be known by the look of astuteness that his sitters seem to bear. The smiling gentleman who showed at the R.P.S. Louis Windmuller, by name, is here, and is well matched in strong characterisation by another gentleman, who ought to be Meissonier, the French painter, if he is not. Mr. Macdonald delights in strong work and powerful contrasts.

### Garro and Hall.

Oval trimming, dainty mounting, and softness of effect suit

well the languishing charms of a head and bust by G. Garro, of Boston. Another head and bust at full face by the same worker has a light background, whilst the head is strong in its tones. The mean between these two extremes lies in the drapery of the bust, which is in soft undemonstrative tones. The result is a print of the utmost strength, sparkle and softness. What could be better adapted to lure the cultivated Philistine sitter?

Handiwork is again somewhat aggressively evident in the clever full-length, by L. A. Steffens, of Chicago. The shadow upon the wall and the reflections in a floor supposed to be polished are neither pleasing nor convincing, and the outline of one light dress is made hard and "cheap" by the added work. Apart from these defects, however, the figure is stately and winning.

Another piece of work more remarkable than pleasing to my captious eye, though I do not doubt that it wins many admirers, is a furniture-piece, wherein the sitters with difficulty hold their own, by H. Hall (Buffalo). So strong are the contrasts in this, that the effect is almost reduced to one of sheer black and white. Perhaps, firelight is simulated. Of course, the thing is very striking, and would be sure to attract, but it strikes me harder than I like. The same photographer has full-length ladies and the best part of a Gibson girl, and these have backgrounds either quite empty or slightly tinted with a touch of water-colour. His finest work for quality is a face, neck, shoulder, and bust, a little less than in profile, and oval-trimmed. Better as portraiture is a beautiful profile in full tone, across which loose and bright hair is allowed to float. This is daringly done, as the hair is quite loose in focus. There are other "fetching" things by J. H. Field (Berlin, Wis.), who is a great believer in the effect of tulle as drapery. J. Parrot (Fort Mayne) also has a swathing of tulle round a fat little naked boy. The splendidly decorative head by R. Eickemeyer, Jr. (New York), is already known to Londoners.

The most attractive of the prints by J. E. Greene (Boston) is a full-length figure close to a wall, whereon a side light plays rather acutely. It gives charming gradation in the background, and illuminates the upper part of the lady's figure, whilst the rest is in a clear low tone. The effect is highly pictorial.

The visitor will find many other examples worthy of his attention which have necessarily been passed over by me; and I am convinced that his own study and judgment will be of greater service to him than these remarks of mine. From the trade point of view, of course, I do not know what I am talking about, and am prepared to be told so—but from the point of view of an onlooker, and as a possible or typical customer, my likes and dislikes may be judged to be mildly interesting.

F. C. TELNEY.

## COLOURING PHOTOGRAPHS BY THE PIETZNER METHOD.

THE following article from our Viennese contemporary, the "Freie Photographen Zeitung," amplifies the particulars of the patented process of Herr Pietzner which appeared on the publication of the latter's complete specification in our issue of November 9, 1906:—

Statements about colour photography always excite general interest both in technical and general circles, because it is on these lines that the photographer will reproduce Nature more correctly. Even if we say that colour photography is still a problem to be solved, and that no satisfactory solution has yet been attained, we can approach by some methods very close to the multiplicity of colours in Nature, yet the goal will always remain unreached so long as the personal equation and skill remain as the most potent factors in attaining this end.

This not only applies to all three-colour methods, but much more

so to all the numerous methods of colouring which of late years have been published as "colour photography." They are incorrectly so-called, and should rather be known as coloured photographs, as their aim is to convert any photograph by treatment with chemicals or pigments into a coloured image.

### Colouring by an Applied Film.

About six months ago an announcement was made in the technical Press that Pietzner, a well-known photographer in Vienna, had succeeded in working out a process of "colour photographing" which—as stated in the prospectus—"had been patented in all civilised countries, and that would probably create a sensation in all photographic circles." When the first results were published it was at once seen to be by no means so sensational, for although the pic-

tures made by this method gave one a very good impression, every one recognised at once that they were no photographs in natural colours, but merely collodion prints with a backing of oil colours, which appeared to be on linen. Actually, there is little new in the method to be called sensational or patentable, for in the 'seventies photographs with an oil colour backing were sold as "chromophotographs." These differed from the new colour photographs in that they were squeegeed to glass, and then coloured.

As it may interest many readers to learn how Pietzner's colour photographs are produced, I will proceed to explain.

As in the old chromophotographs, Pietzner's process consists in the transfer of a coloured photographic film on to a painted photograph or other support. This is effected so that the contact between the two painted images is very close, softer effects than hitherto being thus obtained. The outlines of the photograph are traced out, and this tracing transferred to a support of linen, wood, paper, leather, ivory, or metal. It would be better, instead of using a tracing, to mount a second photograph on the support.

To make the upper picture, stripping collodion paper should be used. The print should be finished in the usual way, and then transferred to glass or celluloid, so that it can be subsequently stripped from the same. In order to do this, the glass, celluloid, or paper should be coated with gelatine solution to which is added tannin, formaline or chrome alum. This hardening agent should prevent the expansion or solution of the gelatine. If the stripping collodion print is now squeegeed under water on to the hardened gelatine film, taking care to avoid air bubbles, the dimensions of the film will remain unchanged, and thus the outlines of this upper picture will coincide more exactly with those of the image on the support.

#### Stripping the Collodion Film.

It is essential to ensure that the collodion image can be subsequently stripped from the hardened gelatine. To this end the

latter is coated when dry with shellac solution, allowed to dry, and then painted with wax dissolved in ether. On this coating the collodion picture can be squeegeed, and when it is ironed with a moderately warm flat iron it will adhere, and the paper can be stripped. The film can again be stripped by means of heat.

Before further manipulations are proceeded with the ground image is coloured with tube oil colours, and these smoothed down with a suitable tool. This is necessary, because, if the painted surface be too rough, the picture will look unsatisfactory. In order to control this work, the upper image which was squeegeed to the gelatine should be superimposed from time to time to see how it looks, and whether corrections are necessary.

When the painting is finished, the stripped collodion picture is brought by means of some mountant into accurate register. For this a solution of shellac or gelatine, with a sufficient addition of acetone, can be used. The acetone softens the celluloid film without dissolving it, and renders the penetration of the oil colours into the upper picture possible, which is very important, because by this means an excellent effect of colour is obtained, and an intimate contact between the two pictures. Afterwards the gelatine transfer surface can be stripped, and one has now a coloured photograph of brilliant colour effect, which is similar to an oil painting. This can now be varnished.

It should be noted that the mountant should be merely spread on the surface of the lower picture. If delicate miniature portraits are required, the stripped collodion image should be first softened with acetone, and then the details, such as the lips, eyes, ears, and gold ornaments, be painted. After renewed fixing with acetone, gelatine, or shellac solution, it should be transferred to the coloured lowered image.

With this process imitations of oil painting can be prepared on canvas, and imitations of water colours on paper and silk.

GUSTAV WALTER.

## STANDARD FORMULÆ.

It would be extremely interesting to know how many plate and paper users employ the special formulæ which are recommended by the makers. Also one naturally wonders why there is such a multiplicity of formulæ when in practice. It is found that, except in abnormal cases, equally good results are obtainable on various makes of papers and plates with one particular developer. Does not this naturally lead one to think that there is no particular virtue in a particular formula, and if so, would it not be possible to frame a developer which should be applicable to any plate or paper?

Certainly this method would considerably simplify the matter for all users of sensitive materials, and it ought to do the same for the makers. The former would know that he need only use a developer he was accustomed to, no matter whose plates or paper he might want to try, and the latter would certainly save considerably by the absence of a lot of printed matter, a great deal of which at the present time goes to litter up one's dark room.

Desiring recently to try a particular brand of plate, I naturally examined the directions for use, and had to sit down with pencil and paper to calculate out what was the actual composition of the pyro-soda developer recommended in grammes per litre, as I always use the metric system. Suddenly I thought of the "Almanac," and found that there it was done for me. After using the maker's pet formula I then tried the Hurter and Driffield standard pyro-soda developer, and found, except for a higher *k*, or more rapid development, the results were the same.

From this fact I was led to examine other pyro-soda developers, and finally reduced them to the same proportion, and although I do not pretend to have examined all the plates and developers recommended, I have tested six and found no practical difference in results. Why, then, should makers and users of plates not adopt a standard pyro-soda developer?

The following table gives the constitution of the various developers

in parts per 1,000, which, if halved, may be practically considered as "grains per ounce."

	Pyro.	Sodium Sulphite	Sodium Carbonate	Potassium Bromide	Remarks.
Austin Edwards.....	6.25	62.5	58.5	—	Nitric Acid .025
Cadett and Neill .....	5.5	52	22	—	Citric Acid .09
Elliott .....	6	56	57	1	Nitric Acid .25
Gem .....	10	80	60	—	Metabisulphite 5
Griffin .....	7	50	50	115	—
Ilford .....	7	50	50	1.2	Mean formula
Imperial .....	6.225	50	50	.975	Metabisulphite 1.5
Eastman .....	7.5	30	30	1	1
Lumière .....	5.6	32	20	—	Nitric Acid .4
Marion .....	6.25	50	50	.075	Sulphuric Acid .075
Mawson .....	6.875	70	55	—	Metabisulphite 1.75
Paget .....	6.25	46	46	—	—
Rajet .....	6.25	50	50	.5	Metabisulphite 1.75
Wellington .....	5.47	54	43.75	—	Citric Acid .5
Wratten .....	6.5	37.5	37.5	—	75
Agfa .....	7	50	50	—	Sulphurous Acid 7.5

Under the heading of "Remarks" are given the acids or acid salts used as additional preservatives in the pyro solution. "Mean formula" against Ilford refers to a mean developer between their strongest and weakest (in pyro) formula.

The mean, small fractions being omitted, of the above developers is given below, and against it Hurter and Driffield's standard pyro developer.

	Mean Developer.	H. and D. Standard.
Pyro .....	6.6	8
Sulphite .....	50	40
Carbonate .....	45	40
Water .....	1,000	1,000

The bromide has been neglected, as apparently eight plate makers

advise it, and eight do not. If it is considered desirable to include this, the quantity would be 0.5 parts per 1,000.

Is there any serious objection to the adoption of either of these formulæ as the standard pyro-soda developer?

Having proceeded thus far, I was led on to examine the question of a standard metol-hydroquinone developer, first as regards bromide and gaslight papers alone, and then it occurred to me that it would be possible to compound one which could be used both for negative and positive work. This was found to be a little more complicated, because one or two makers appear to prefer potassium carbonate or hydrate to sodium carbonate.

#### NEGATIVE DEVELOPERS.

	Metol.	Hydroquinone.	Sodium Sulphite.	Sodium Carbonate.	Potassium Bromide	Remarks.
Cadett .....	1.875	1.875	15	15	1	
Griffin .....	3	12.5	100	172	5	
Imperial (Single Sol.) .....	5.5	4.5	57	57	3	
Kodak .....	1	1.75	37.5	25	5	
Marion .....	3	3	40			
Wratten .....	1.6	6	16.6	16.6		
Agfa .....	5	7.5	100		1	

The following gives the bromide paper developers treated in the same way:—

	Metol.	Hydroquinone.	Sodium Sulphite.	Sodium Carbonate.	Potassium Carbonate.	Potassium Bromide.
Cadett .....	3	1.5	10	12.5	—	1.5
Elliott .....	6	4	75	—	25	1.5
Iford .....	2.5	1.4	25	12.5	—	2
Kodak .....	9	3.5	36	36	—	2
Kajar .....	9	3.45	37.5	37.5	—	2
Rotary .....	5.8	4.6	58	58	—	2.9
Wellington .....	5	1.5	50	—	10	1

#### GASLIGHT DEVELOPERS.

	Metol.	Hydroquinone.	Sodium Sulphite.	Sodium Carbonate	Potassium Bromide.
Cadett .....	2	6.5	65	65	21
Elliott .....	1.75	7	75	70	7.1
Iford .....	1	4.6	60	50	25
Illingworth .....	2.6	6	44	80	7
Dekko .....	1.8	7	72	72	4
Leto .....	2	6	25	130	98
Rotary .....	1.8	6.3	60	125	35
Wellington .....	2	6	70	70	6

The following shows, as far as possible, the mean of these tables and the mean of the three developers:—

	Negative.	Bromide.	Gaslight	Mean.
Metol .....	3	3.2	1.9	2.8
Hydroquinone .....	4.5	2.85	6.2	5.2
Sulphite .....	53	42	56	50
Sodium Carbonate .....	57	31.3	83	57
Or Potassium Carbonate .....		17.5		
Bromide .....	5	1.3	4	7

A developer made up exactly as the "mean" was found to work well, not only with plates, but also for bromide and gaslight papers, so far as I have been able to test it. To try it with all plates and papers would be a serious task, and useless, unless under exact test conditions, which at present are beyond my power.

It is possibly hopeless to dream of makers adopting such standard formulæ, for there must obviously be some reason, occult or otherwise, that induces such wide variations as are to be seen in the above tables. Users of sensitive materials can, of course, please themselves. Personally, I should like to know whether there is anything so different in the composition of plates and papers which shall make them not amenable to a common formula, such as the above. Certainly the adoption of standard formulæ, which need not be confined to development, but could be equally applied to printing out materials, would make the path, of the beginner at least, far easier than it is now.

A. GASCOIGNE.

## CARBON PRINTING IN AMERICA.

THE attitude of the American professional photographers towards the modern printing processes is a question of no little interest to ourselves in this country, where a much greater choice in printing media is open than in America. Collodio-chloride paper has dominated the market and the practice of photographers for years past in the States, and it is only of late that the newer processes have been taken up at all largely. The following account therefore (in "Wilson's Magazine") of the increasing use which is being made of carbon speaks for itself of the value of the pigmentary process in the hands of the professional photographer.

A great deal has been written of late, to encourage the professional, as well as amateur photographer, to make use of the superior advantages offered by the modern methods of carbon printing, to improve the artistic qualities, as well as permanency of his work, and as a means by which to uplift the standard of his profession to a higher place among the arts, where it justly belongs.

The supremacy and great capabilities of the modern carbon process, and its adaptability to the most varied requirements of our present day photography, have been amply demonstrated by men of high professional standing everywhere, which ought to be a sufficient recommendation to induce every progressive photographer in the country to at once adopt this beautiful process for at least their better class of work.

It is, indeed, gratifying to note the progress made in carbon printing within the past year and the encouragement offered to those who are striving to better and improve the methods that yet appear difficult to the ordinary worker.

In Europe, every new invention—every improvement is applauded by the press; which, like a pat on the shoulder by a good friend, encourages and gives new impulse to further efforts in improving this valuable process.

Perhaps in no other country has carbon printing made such rapid progress as in America. The great artistic beauty and indisputable permanency of carbon pictures especially, appeals with irresistible

force to every honest and upright photographer who has the good of his profession at heart.

If we look back over the work of our leading professionals of to-day, we find invariably that nearly all the work they stake their reputation on is invariably printed in carbon. It is also a notable fact, that nearly all the work made for permanent exhibits, salons, art galleries, and pictures intended for historical purposes, are printed in carbon. For the latter, especially, the indisputable permanency of carbon pictures, is a matter of inestimable value, and every photographer who is entrusted with the making of pictures that are to be handed down to future generations as historic mementoes of past events, should, by all means, print them in carbon.

I was never impressed with the truth and great importance of this fact as I was when I recently called on the secretary of an historical society, to show him the great value of carbon pictures for historical purposes. When I compared my carbon pictures with the yellow and faded pictures on the walls, and explained their merits, as to permanency, he at once recognised the truth of my assertions, and was profuse in acknowledging the same, and promised that henceforth all the work that is done for the society must be printed in carbon.

For a number of years past I have come in contact with a great many professionals, as well as advanced amateur, photographers, which gave me an opportunity to observe the growing interest and

the increasing numbers in the ranks of carbon printers in this country.

A few years ago there were perhaps a dozen, all told, and thousands of photographers who had never seen a carbon picture or knew the first principle of the process. To-day there are at least a thousand, and their number is fast increasing, a fact to which I can testify with a long list of names, including some of the most prominent professionals in the country.

The advantages and supremacy of the modern carbon process, in its present state of perfection, are now universally recognised by the profession the world over; and American influence has also proven itself to be a great factor, even in the progress of the world's photography—a fact which is evinced by the great demand from abroad for our books, covering the newest methods in carbon photography. The most gratifying results, however, are shown by our own professionals. Every day the mails contain letters from photographers who have recently taken up the carbon process, and who express their great pleasure and delight at the results they have obtained, after a short acquaintance with the process.

At the present writing I have before me a picture of an old man, a most exquisite piece of work in sepia, and one that would do credit to the best professional carbon printer in the country. It was sent to me by a young man who, three months ago, knew nothing whatever about the process. In his letter he says:—"I am not conceited enough to make any great pretensions as a carbon printer; I merely want to show you where I am at, and express my great pleasure and delight at the results I have obtained in the few months I have attempted to do my own carbon printing."

A Southern photographer writes:—"I wish to thank you for being so persistent in urging me to take up the carbon process. I had never dreamed that such grand artistic work could be produced by such simple means, and I am very sorry now that I did not begin sooner. Many of the fine pictures I have made within the past year, I am convinced, would have been greatly improved, and I would rest assured that they were absolutely permanent."

A leading professional from Iowa writes:—"It seems almost foolish for a man to get stuck on his own work; but I must confess, since I have taken to carbon printing, I spend more time in admiring my own work than I can really afford. There is something so extremely fascinating about these pictures, that one will study and admire, and drink in the beauty of this work, until he is entirely oblivious of himself. Such depth and richness of tone, and such exquisite rendering of values, even to the smallest details, certainly cannot be equalled by any other process."

"I am so charmed with this beautiful work that I want to tell you that if I never sold a single carbon picture, I would consider the pleasure and great satisfaction I have derived therefrom the greatest compensation for the time and money I have spent in accomplishing these beautiful results."

I give the above to show the enthusiasm and spirit with which the American photographer, when his interest is awakened, enters upon a field of photography comparatively new to him, and conquers every difficulty with a zeal peculiar to him. In another year I hope to see an increase of several thousand more, and then the time is not far distant when every photographer in the country will understand the carbon process.

A. M. MARTON.

## ARTIFICIAL NEGATIVES.

(A Contribution to Liesegang's "Photographischer Almanach.")

By this term is meant such negatives as are prepared by hand drawing on prepared glass plates.

Anyone who possesses sufficient skill in drawing can produce such negatives, as the work is precisely the same as drawing with the pen on paper. The first trial will prove how the graving needle must be used, and at the worst the plate only requires regrounding when the drawing is a failure.

The artificial negatives have the advantage over those produced by photography in that the drawing is absolutely clear glass and transparent, which is absolutely impossible to obtain in the ordinary way.

If it is desired to produce a negative from any line drawing, picture, or half-tone photograph, there is no better way than the artificial negative, which can be made as follows:—

From the subject, the line drawing, or photographic print, a copy as accurate as possible should be made on transparent tracing paper with black ink and a pen, then this can be traced, either reversed or not on the ground plate, by placing under the transparent print a sheet of tissue paper rubbed with powdered English red, and then tracing over all the lines with a sharp lead pencil, so that they are transferred to the coated plate.

In order that the transparent print may not shift, it should be fastened at its top edge with wax, and then one can lift it up to see the progress of the work as often as one likes.

### Tools for the Work.

As regards the actual etching, no advice can be given, for here the skill in drawing comes into play. A good English sewing needle of the largest size (mounted in a round handle like a lead pencil) can be used as a graver. With this point all fine lines can be worked in, and the needle should be held like a pen. Broader spaces can be scraped out with a sharp-pointed pocket knife, with which it is possible to obtain both broad and fine lines according to the position of the hand. The whole work goes on easily, as the etching ground presents no resistance, and the more filled one is in drawing the quicker the work is done. Excellent line blocks can be made from such negatives.

The graver must always be kept very sharp, and a whetstone and some machine oil should be kept close at hand.

### An Etching Ground.

The most important point in this process is the etching ground, which must have the necessary resistance and elasticity with absolute opacity. It must not break away from the glass, and lines at the most acute angles for shading must be possible. Many formulae have been given for such a preparation. I use one of the following composition:—

Canada balsam .....	1 part.
Rectified turpentine .....	2 parts.
Liquid siccativ .....	$\frac{1}{4}$ to $\frac{1}{2}$ part.

These are thoroughly mixed together and as much lampblack or pine soot added as will give it the consistency of an ointment. The glass should be evenly coated with this by the aid of a badger-hair softener. The plate should be held up against the window so as to see that there are no pinholes in the coating, as the plate must be absolutely opaque. Care should also be taken to see that the film is as even as possible.

If the ground should become thick during the coating, a little turpentine should be added. The plates will take several hours to dry, and when they are no longer sticky they can be used. First of all the plate should be dusted with powdered graphite and a soft pad. After well dusting it is then ready for use.

In order to see every line as it is made it is advisable to use a retouching desk and reflect the light through the plate with a sheet of white paper. The lines will then appear white on the black ground, and the effect of each can be at once seen.

If errors occur they may be blocked out with a fine brush charged with the ground, but the plate must be quite dry when this is done. A ruler may be used for straight lines or outlines; even circles or curves may be put in by means of sectors, etc., only care should be taken when using these not to damage the ground.

When the etching is finished it should be examined against a window, and if everything is satisfactory it is ready for use.

The etched lines should be clear and sharp in order to give good impressions, and it is therefore advisable during the etching to use a broad soft brush to remove the little bits that are scraped up, so that they do not adhere to the lines.

### A Modified Formula.

Another etching ground consists of

Syrian asphalt (powdered) .....	50 parts.
Golden-yellow Venice turpentine .....	10-12 parts.
Linseed varnish or oil .....	15 parts.
Oil of turpentine .....	15 parts.

The asphalt, Venice turpentine, and turpentine should be placed in an enamelled saucepan on a moderate fire and boiled and stirred till everything is completely dissolved; then it should be removed and the linseed oil added in a thin stream and continual stirring. To the mass should be added enough lampblack till it is of the consistency of salve and a deep black. The well-cleaned glass plate should be evenly coated with this till opaque, allowed to dry and rubbed over with a little lampblack mixed with a little gum water. At first the resinous ground will repel this, but by repeated coating it will adhere.

Care should be taken that the ground is not too thick, otherwise the lines will not be clean, but one or two trials will soon tell one the correct thickness.

The gum coating can also be used for the Canada balsam ground if the latter is not sufficiently opaque. The resin ground should be kept in a well-corked wide-mouthed bottle.

Old negatives cleaned from their films can be used, and it is advisable to clean them with diluted hydrochloric acid and then with acetic acid and chalk, and, finally, well washed and dried.

JOHANN MAI.

### DEATH OF MR. SEBASTIAN DAVIS.

A NAME that was very familiar to the past generation of photographers disappears with the death of Mr. T. Sebastian Davis. The deceased gentleman, who until quite recently was in full possession of his usual health, had been a member of the Royal Photographic Society for fifty years, and during a great part of that time, had taken an active interest in the Society's affairs. His interest in all branches of photographic work was maintained for a long period of years, and his experience, an extremely wide one in matters technical, was always freely at the disposal of those to whom it might be of value. In his younger days, Mr. Davis was engaged in chemical industry, and for many years had been a Fellow of the Chemical Society. At the time of his death he was in his seventy-ninth year.

### HEARTLESS CANVASSING FRAUDS.

ROBERT GIBSON, 48, Queen Street, was brought up on remand at the Wigan Borough Police Court last week charged with obtaining money by false pretences.

The Chief Constable said there were only two cases brought against the prisoner, but he seemed to have been practising for nearly twelve months a course of systematic frauds, collecting subscriptions weekly for enlargements of photographs he obtained from different people, but never executing the orders, and making excuses when he called that the weather had not been suitable for enlarging or developing, or some other process. Some of the people had been bled to the extent of large amounts, as one poor woman to the extent of £1 7s. in weekly contributions. No more deliberate frauds could have been practised on these poor people. Gibson had used the names of many people in the town, though he (Mr. Hardy) did not wish to mention them unnecessarily, and the prisoner ought to have been ashamed to drag them in. He had been well brought up and was well educated, and had been respectable. It was only a short time ago that there was a case of two parents being brought up for neglect of children, and this man it was proved was living in their house and would not leave it, but the magistrates ordered that he should be bundled out. He had been obtaining subscriptions from poor people of 6d. and 1s. a week without any hope whatever of giving people any value for their money.

Mrs. Ellen Dunbar said on the 22nd ult. the prisoner called at her house canvassing for orders for photograph enlargements. She had been married twice, and she was anxious to obtain an enlarged photograph of her first husband. The prisoner told her the cost ought to be 35s., but he would charge her 30s. The terms were for payment of that sum at a shilling a week. She had paid him 6d. or 1s. each time. He kept calling, sometimes missing about three weeks. The last time he called was on the 26th of November last year. Altogether

she had paid him 6s. He came drunk sometimes, and that made her suspicious of him. She had been done once by a fellow from Manchester, but as the prisoner was in Wigan she thought it was all right. It was not until the police called that she found out that there was a fraud.

A card was produced which the prisoner had used, on which appeared the following:—Wigan and District Oil-Painting Company, Robert A. Gibson. Private address: George Street, Wigan. Sitting address: 25, Mesnes Street, opposite the Market Hall. Canvasser's name, R.G., £1 10s." The witness identified this card.

The Prisoner: Did I explain that sittings only took place at Brazendale's?

Witness: Yes.

By the Magistrates' Clerk: He said he was manager for Moot Hall Chambers, but that the sittings were at Brazendale's.

James George Brazendale, photographer, 25, Mesnes Street, said the prisoner, about the last week in February, 1906, came to him to execute two orders for him, for which he paid 12s. 6d. Witness never authorised him to put on his card that he was his manager or that he had sittings at witness's place, or to use his name on the card. When witness heard something a few weeks after he went to see the prisoner, and asked him what he meant by putting witness's address on his card. The prisoner said he had it for sittings only on the card, and did not think witness would mind. He had one person sitting at witness's place before he went to see him.

By the Magistrates' Clerk: There was no arrangement made for sittings to take place any more than for casual customers walking in.

By the Chief Constable: Witness told him the cards must be destroyed, as he would not allow the prisoner to use them, and he said afterwards that they had been destroyed, but witness had since learnt that they had not. He had never been employed by witness as manager or agent. Witness did not know of any such company as the "Wigan and District Oil-Painting Company."

The Prisoner (to the witness): Did I not make arrangements with you to take sittings for me?—No.

Detective Gordon said he took Gibson in custody under a warrant, and charged him with obtaining 6s. by false pretences from Ellen Dunbar, between the 22nd of January and the 26th of November, 1906. He replied, "She would have got her picture when it became due." Witness found in Gibson's possession the book produced, and had interviewed many people whose names appeared on it.

The prisoner pleaded guilty.

The Chief Constable said he was prepared to call a witness as to the payment of £1 6s. to the prisoner. He referred to numerous other cases, mentioning that of Ellen Tocker, 2, Zulu Street, who had paid £1 6s. in contributions from the 3rd of March until the 26th of November. He had never been near Mesnes Street, Mr. Hardy remarked, since February.

Alderman Richards: I suppose all these people will lose their money?

The Chief Constable: It is a clean sweep for a lot of them. They will lose everything.

The Prisoner: I do not wish them to lose it. It is a matter of time.

The Chief Constable: He has been up twice for drunkenness.

The Bench did not hear any further evidence, and sent Gibson to gaol for two months.

### THE CONVENTION WINTER REUNION.

THE Convention Social Evening took place on Friday last in the Galleries of the Royal Society of British Artists, Suffolk Street, Pall Mall, S.W., where a very fine exhibition of modern painting was on view. The programme consisted of a reception by the President, a vocal and instrumental concert (under the direction of Mr. F. A. Bridge), to which Miss Margot Severn, and Mr. J. R. Bovett contributed some enjoyable songs, Miss Louise Ferrar some charming violin solos, and Professor Otto Sondermann a very strikingly original pianoforte fantasia on some themes by Wagner. Miss Alice Kent, L.R.A.M., was the accompanist.

After a "refreshing" interval came a little dance of nine numbers, Mr. Alfred Ellis and Mr. Walter Potter acting as M.C.s, and Miss Irenie Harding as pianist.

About 140 invitations had been accepted, and among those present were:—Mr. E. J. Humphery (President) and Mrs. Humphery, Mr. F. A. Bridge (Hon. Sec.) and Mrs. Bridge, Mr. W. T. Carless (Hon.

Local Sec. Hereford Meeting), Mr. and Mrs. Alfred Ellis, Miss Effie Ellis, Mr. Douglas Ellis, Mr. Alex. Corbett and Miss Lillie Corbett, Mr. M. Black and Miss Black, Mr. and Mrs. Beeching and Miss Beeching, Mr. and Mrs. W. H. White and Miss White, Mr. E. J. Walker, Mr. and Mrs. Walter F. Potter and Miss Potter, Mr. and Mrs. Guy Dancy, Miss Tarry, Mr. W. H. White, Mr. and Mrs. Robert Dixon and Miss Dixon, Mr. Geo. E. Brown, Mr. A. W. Brooks, Mr. Hector Maclean, Miss Maclean, and Miss Sheila Maclean, Mr. and Mrs. E. J. Wall and Miss Wall, Mr. F. J. Mortimer, Mr. A. Horsley Hinton, Mr. P. R. Salmon, Mr. H. Snowden Ward, Mr. J. W. P. Rawlins, Mr. and Mrs. T. K. Grant, Mr. and Mrs. Charles Winter, Mr. J. A. Bovett, Mr. and Mrs. Allworth, Mrs. Thomas Sexton and Miss Sexton, Mr. Thomas Scott, Dr. S. Walshe Owen, Mr. and Mrs. Lawrence Spicer, Mr. and Mrs. R. Lang Sims, Mr. and Mrs. Hedley M. Smith, Mr. and Mrs. Sidney Keith, Mr. G. B. Bainbridge, Mr. and Mrs. O. S. Dawson, Mr. W. H. Smith, Mr. W. E. Dummore, Mr. C. J. Aldham, Mr. S. H. Wratten, Mr. Geo. Glanville, Miss Margot Severn, M. Paul Berton, Mr. and Mrs. R. Meynell, Professor and Mrs. O. Sondermann, Mr. Martin Jacoetto, Mr. and Mrs. Bartley Finn, Mr. A. Mackie, Mr. and Mrs. R. R. Beard, Mr. A. W. Green, Mr. R. M. Mayell, Mr. and Mrs. A. C. Baldwin, Mrs. C. M. Gaze and Miss Olive Gaze, Mr. J. Hernaman, Mr. H. J. Harding, Miss Irene Harding and Miss Dora Harding, Mr. Hans Müller, Miss Gabelle, Mrs. and Miss Louise Ferraris, Mr. and Mrs. G. W. Atkins, Mr. W. R. Dunn, Mr. A. Dunn, Mrs. and Miss Beaumont, Mr. S. Barker, Mr. C. L. Burdick, etc.

The singing of the National Anthem about 11.45 brought a very enjoyable evening to a close.

## Exhibitions.

### PHOTOGRAPHS BY AFFILIATION MEMBERS AT THE ROYAL PHOTOGRAPHIC SOCIETY.

THE present house exhibition at Russell Square consists of a collection of prints made by members of affiliated societies. A number of plaques are awarded by the Affiliation, the judges being Messrs. Furlay Lewis, J. A. Sinclair, E. T. Holding, C. H. Oakden, and J. T. Ashby; the above gentleman making up, with Mr. Reginald Craigie, the board of judges appointed by the Affiliation. In addition to the plaques awarded individually to the exhibitors, certificates have been granted to societies on a system of marking the individual prints. The collection includes a very fair proportion of promising work, all of which, with scarcely an exception, is technically good, and there are pictures by a number of men who have not yet been heard of prominently in exhibition circles, but who, from their technical command of processes, should gain distinction in the future. No. 17, "Early Morn," by W. A. I. Hensler, is a print of very simple composition with a delightful suggestion of early morning mist. Mr. E. R. Bull is well represented in one of his architectural studies, No. 20, and Mr. Kimber, of the Southampton Society, shows us once again, "A Relic of the Past," No. 26. Rothenburg, in Southern Germany, recently extolled by Mr. Shaw, of Manchester, provides the subject of a delightful architectural study by Mr. F. Mordaunt. No. 36, "The Lock Keeper's House," is quite one of the most instructive photographs in the exhibition, for it would be difficult to find a better example of "the picture within a picture." If the print be cut almost exactly vertically down the middle, one obtains two exceedingly good pieces of composition. As it stands, the photograph is a horrible example of balance run mad. As notable a work as any on the walls is No. 42, "The Cauldron," the subject a waterfall, possibly in the Lake District, but treated in a fine imaginative fashion. We hope to see more of Messrs. H. and F. Read's work. The Exhibition will remain open until February 23, after which the photographs are to be circulated among affiliated societies.

"THE British Optical Almanac and Opticians' Year-Book" for 1907 is to hand, and, as in previous years, contains a large amount of information which should be of considerable value to those engaged in the optical trade. It is issued from the offices of "The Optical Journal," Temple House, Temple Avenue, E.C., and is supplied gratis and post free to all subscribers.

### FORTHCOMING EXHIBITIONS.

1907.

January 14 to 26: Royal Institute of Fine Arts.—Sec., J. Lizars, 101, Buchanan Street, Glasgow.

January 18 to 31: Paisley Philo. Institute and Photographic Society.—Sec., Hugh F. Hamilton, Glaisnock, Bank Street, Paisley, Scotland.

January 23 to 25: Dover Photographic Society. Secretary, J. W. Howells, 6, Gladstone Terrace, Dover.

January 24 to 25: South Essex Camera Club.—Sec., T. Mitchell, 180, Browning Street, Manor Park, E.

January 31 to February 1: Isle of Wight Photographic Society.—Sec., H. G. Morgan Hobbs, Sunnyside, Watergate Road, Newport, I.W.

January 31 to February 2: Nelson Photographic Society.—Sec., Henry H. Beetham, 98, Brunswick Street, Nelson.

February 5 to 7: Salisbury Camera Club. Entries close January 22.—Sec., T. S. Broom, Farnett, Salisbury.

February 6 to 7: Cowes Camera Club. Entries close January 23.—E. E. Vincent, 4, High Street, Cowes, I.W.

February 7 to 9: Borough of Tynemouth Photographic Society. Entries close January 25.—Sec., J. R. Johnstone, 159, Linskill Street, North Shields.

February 11 to 14: Cripplegate Photographic Society. Entries close January 28.—Sec., J. B. Parnham, Chagford, Old Church Road, Chingford.

February 12 to 23: Sheffield Photographic Society. Entries close January 26.—Sec., J. W. Wright, 62, Vale Road, Sheffield.

February 13 to 15: Northern Tasmanian Camera Club.—Sec., F. Styant-Brawne, 112, Brisbane Street, Launceston, Tasmania.

February 15: Cardiff Photographic Society.—Hon. sec., A. E. Harris, 44, Partridge Road, Cardiff.

February 20 and 21: Royal Albert Institute, Windsor.—Hon. Sec., Mr. J. W. Gooch, 9, High Street, Windsor.

February 20 to 21: Canterbury Camera Club. Entries close February 9.—Sec., G. T. Hobbs, 3, Norman Road, Canterbury.

February 22 to March 4: Norwich and District Photographic Society.—Sec., J. T. Tanner, The Lodge, Norwich.

February 23 to March 2: Birmingham Photographic Society. Entries close February 12.—Sec., Lewis Lloyd, Norwich Union Chambers, Birmingham.

February 23 to March 9: Edinburgh Photographic Society. Entries close February 9.—Sec., H. Stewart Wallace, W.S., 77, George Street, Edinburgh.

February 23 to March 16: Scottish National Salon. Entries close January 31.—Sec., Robert Milne, Linndale, Potterhill, Paisley.

February 25 to 28: Worthing Camera Club. Entries close February 16.—Sec., E. F. H. Crouch, 11, South Street, Worthing.

February 26 to March 2: Norwich and District Photographic Society. Entries close February 12.—Sec., J. T. Tanner, The Lodge, Bowthorpe Road, Norwich.

February 27 to March 2: Nottingham Camera Club. Entries close February 14.—G. R. Cranch, St. Jude's Avenue, Nottingham.

February 28 to March 7: Queen's Park Amateur Photographic Society. Entries close February 14.—Sec., J. Moir, 644, Cathcart Road, Glasgow.

March 2 to 9: South London Photographic Society.—Sec., W. L. White, Bank House, Ladywell, London.

March 2 to 24: Marseilles Photographic Society.—Sec., M. Cullet, Rue St. Savournin, 38, Marseilles.

March 6 to 8: Aldershot and District Camera Club. Entries close March 2.—Sec., D. Morrison, Kilry, York Crescent, Aldershot.

March 6 to 9: Wearside Camera Club. Entries close February 20.—Octavius C. Wilmot, 297, High Street West, Sunderland.

March 6 to 9: Bolton Amateur Photographic Society. Entries close February 16.—Sec., Gilbert Holt, 187, Deane Church Lane, Bolton.

March 7 to 16: Leicester and Leicestershire Photographic Society. Entries close February 16.—Sec., Lewis Ough, "Fernleigh," St. James' Road, Leicester.

March 14 to 16: Coventry Photographic Club. Entries close March 9.—Sec., T. J. Mercer, 6, Cope Street, Coventry.

March 22 to April 13: Northern Photographic Exhibition. Entries close March 8.—Sec., C. F. Inston, 25, South John Street, Liverpool.

March 23 to April 2.—Glasgow Southern Photographic Association. Entries close March 16.—Sec., Charles Young, 217, Crow Road, Partick, Glasgow.

April 10 to 13: Ilkeston Arts Club, Photographic Section. Entries close March 27.—Sec., A. Smith, 11, Graham Street, Ilkeston.

April 17 to 19: Belfast Y.M.C.A.—Sec., J. W. Bushey, Y.M.C.A. Camera Club, Belfast.

April 25 to 27: Wallasey Amateur Photographic Society. Entries close April 10.—Sec., W. Hayes, 110, Brighton Street, Seacombe.

April 29 to May 14: Photographic Society of Ireland. Entries close April 22.—Sec., R. Benson, 35, Molesworth Street, Dublin.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between January 1 and 5:—

**COLOUR PHOTOGRAPHY.**—No. 32. Improvements in methods of and appliances for utilising Lippmann photographs. Carl Zeiss, a Body Corporate, Jena, Germany.

**COLOUR SCREENS.**—No. 58. Improved method of producing autotypic screen for colour-photography. Robert Krayn, 33, Cannon Street, London.

**SHUTTERS.**—No. 95. Improvements in photographic shutters. Gustav Dietz, Birkbeck Bank Chambers, Southampton Buildings, London.

**COLOUR SCREENS.**—No. 194. Improvements relating to the manufacture of screens for use in colour-photography. Louis Ducos Du Hauron and Raymond De Bercegol, 11, Southampton Buildings, London.

**CINEMATOGRAPHS.**—No. 206. Improvements relating to the synchronous operation of combined cinematographs and phonographs. Leon Gaumont, 7, Southampton Buildings, London.

**BACKGROUNDS.**—No. 303. Improvements in photographic background stands. John William Sagar, 54, Colne Road, Burnley.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**FOCAL-PLANE SHUTTERS.**—No. 13,107, 1906. The invention relates to shutters consisting of two roller blinds, one of which is movable in reference to the other for the purpose of altering the width of the slit. In the shutter, the tapes serving for the adjustment

of blind of one shutter section are adapted to pass along and through the other shutter section, the latter being of such stiffness and special construction as to remain undisturbed when the tapes of the lower section are moved relatively to the upper section. The invention also comprises improved means for winding the tapes and shutter, and also for tripping the upper roll while means are arranged for locking the slot aperture adjusting mechanism after it has been once set. The lower shutter section a

is wound upon the usual spring roll *b*. The upper shutter section *c* is wound upon the tripping roll *d* which has a ratchet wheel *e* engaged by a tripping pawl *f*. Slit adjusting tapes *g*, attached to the lower shutter section, pass loosely through passage ways or hems in the upper shutter section, and thence through slots *h* in the tripping roll to winding rolls *i*, *i*, on the endwise movable roll shaft *j*. The shutter section *c* is to be of such character that when it is down and the winding rolls *i* are rotated, tapes *g* will draw the edge of the lower shutter section toward the edge of section *c* to reduce the width of the slit, or permit the edge of *a* to recede from that of *c* to increase the width of the slit without disarrangement of the shutter section *c*. This characteristic of the devices is the primary feature of this invention.—Louis Borsum, 953, Woodland Avenue, Plainfield, New Jersey, U.S.A.

**INVISIBLE PRINTING.**—No. 5,183, 1906. This invention relates to a process of printing invisibly, views, designs, or other matter which can be rendered visible by heat on paper, postcards, or the like, the object being to provide interesting and entertaining printed designs, views, and subject matter. The inventors invisibly print on or apply to the paper, views, etc., with a preparation of sulphuric acid otherwise termed "invisible ink," and consisting of, say, one part of sulphuric acid to about ten parts of water. The type blocks are made of rubber, or they may be coated with india-rubber and applied to the paper in the usual way; that is to say, the chemical is applied to the paper by the block which is of any desired form. The designs or other matter is previously printed on the paper with visible ink, missing portions being filled in with invisible ink. On heating the paper the matter printed by means of the rubber blocks and sulphuric acid will become visible. Valentine and Sons, Ltd., 152 and 154, Perth Road, Dundee; and Alexander Conradt Smith, 95, South Street, St. Andrews, Fife.

**PANORAMIC CAMERAS.**—No. 12,813, 1906. The invention consists of a camera for panoramic photography wherein separate mechanisms are provided for moving (1) the film, and (2) the camera. The main motive power acts to rotate the camera, whilst the other separate spring motor rotates the spool upon which the sensitive material is wound up, thereby obtaining a regular and uniform movement of the camera, and a uniform displacement of the sensitive material before the lens. August Müller and Johann Klein, Rhöndorf, Germany.

**CLOCKWORK RELEASE FOR SHUTTERS.**—No. 27,125, 1905. The invention is to enable a photographer to expose a plate on the lapse of a certain period of time after starting the mechanism. Two methods are employed, the first consisting of a train of clockwork wheels actuated by a spring. As shown in the figure, one end of the spindle of one of the wheels is elongated, and near the end a lever is attached. In the figure, A represents the lever, and B its attachment to the end of the spindle by the thumb screw, the

thumb screw being screwed on to the end of the spindle. This lever may be placed in any position, such as perpendicular, and then fixed in that position by the thumb screw B. The clockwork being then set in motion, the lever A will revolve with the spindle to which it is attached, and will, when so arranged, press upon the lever (2) of the photographic shutter, and so cause the shutter to operate and expose the negative previously placed ready in the camera. The time which will elapse between the moment of setting the clockwork in motion and the moment

when the end of the lever A presses upon the lever (2) or button of the photographic shutter, may be varied by placing the lever A in different positions, and fixing it in any particular desired position by the thumb screw B previously to setting the clock-work in motion. The further the lever A is fixed in a circular direction from lever (2) the longer will be the time which will elapse before the negative is exposed, and vice versa.

The second method consists of a pneumatic cylinder, a lever attached to the piston of which actuates the shutter. Edward Benjamin Hazleton, 103, Fitzwilliam Street, Sheffield.

**PRINTS FOR REPRODUCTION.**—No. 26,369, 1905. The following process is employed to modify the light and shade of prints intended for half-tone and three-colour reproduction.

The print is attached firmly to a drawing board, and with a steel blade, such as an ordinary pocket-knife (by removing the surface of the print) all the detail wanted in the dark parts of the print is carefully "engraved."

Any missing detail is then drawn in the white, blank parts of the print, with an ordinary lead pencil point.

With waterproof ink applied with a camel hair brush certain parts of the print which it is desirable to keep in the original colour are protected.

When the ink is dry the print is placed on a sheet of glass, and put under a tap of running water until the print is quite saturated.

The wet print still on the glass is then placed into a bath composed of two parts of cyanide of potassium to one part of iodine with three times the quantity of water, and left there for sufficient time to obtain the requisite lightening in the colour of parts of the print unprotected by the ink.

If the time of immersion be too long, or the bath very strong, the parts protected will be hard, and far too strong in tone. For large prints with little detail, treatment with a brush is better than bathing in chemicals. The print is then dried in the usual way.

The process of stopping out and bathing to produce further graduations of tone can be repeated as often as desired.

The waterproof ink can be removed by gently sponging with methylated spirit. The print is then dried.

When dry if any of the engraved parts appear too strong for satisfactory reproduction the finger is rubbed on a stick of crayon and rubbed into the engraved parts. Florence Prout Rowse, 18, Chalk Hill, London Road, New Bushey.

**CINEMATOGRAPH-PHONOGRAPH.**—No. 26,440, 1905. The invention is of a device for starting a phonograph or other talking machine at the correct moment to synchronize with a cinematograph film projected on a screen. The drawings in the specification are necessary for its explanation. W. C. Fairweather, for Eward Thormeyer, 3, Grosse Allée, Hamburg, Germany.

**ROLLER-BLIND SHUTTERS.**—No. 16,353, 1906. The invention relates to a shutter consisting of two portions adjusted to each other and operated by toothed wheels mounted on their spindles with an intervening wheel and provided with clutch devices in connection with the gearing to allow the shutter parts to move relatively to produce an exposure slit between them at the termination of the winding-up movement and the closing of same at the last stage of the return movement of the shutter.

The invention aims to improve the construction of the clutch devices, and describes the mechanism in detail. Tudor Travers Hora, 346, York Road, Wandsworth, London.

## New Trade Names.

**PENGUIN BRAND.**—No. 286,353. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. Hugh Weir Mackenzie, 261, Gairbraid Street, Maryhill, Glasgow. Wholesale ironmonger and hardware merchant. September 20, 1906.

A new photographic publication has appeared in New York in the shape of the "Journal of the Photographic Trades," a monthly periodical, issued by the "National Photographer," New York. The appearance of the journal is apparently the result of a difference between the proprietors of "The Photographer," and the Eastman Kodak Company.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Impressionism.

"Introduce into your pictures" (says Mr. P. Bale Rider, in "The Photographic News") "as much detail as you like, so long as it does not detract from the leading motive. Look at Turner's pictures. He knew how to draw. There is drawing in some of his broadest work as fine as a hair, but it wants looking for; it never obtrudes, it is subordinated to the breadth of effect. Many artists fail here. They have never properly acquired the skill of handling pencil or brush, and excuse their faulty handling by saying that they go for broad impressionism. But only deft craftsmen can paint impressionism effectively. It is not that they cannot put in detail, but they know just how much to leave out. Let us cultivate the knowledge as to how much to leave out."

### In Praise of Gum.

Workers of other processes (says Mr. F. L. Warner, in "The Amateur Photographer") seem to hold the gum-bichromate process (which I am going to advocate as giving power of control in the fullest degree) either in contempt, or else in such respectful awe that they never attempt it. The first class seems to include a number of the older workers, who, I suggest, instead of trying to take the position in the van of modern pictorial progress, should submit to be graceful adornments of a position midway between the sharp-all-over-and-shiny school, prevalent when the science of the art was all-important, and the modern school of pictorial workers. I am convinced that, willing or not, it is this midway sphere that they will, by general consent, be compelled to occupy, and they will only be listened to on matters of science. Must it not in this connection be admitted that the nicely exact mind necessary to the scientist seldom is combined in the same individual with the other state of mind—I hesitate to define it—necessary to the artist, the man of visions?

### Lantern Illuminants.

The light (writes Mr. J. A. Hodges in "Focus") perhaps exercises artistically an even more important influence for good or ill in a lantern show than the screen. Nowadays, the tendency is to use too much light, the result being that not only are the artistic qualities of the slides either lost—or, at any rate, greatly marred, but the glare produces eye-strain by its effect upon the optic nerve, and the audience goes away with a headache. The electric arc, in fact, is most unsuitable, unless of very moderate power, for anything but the largest-sized discs, and when of great intensity not only exerts a harmful influence on the slides physically, but ruins them artistically. It is destructive of colour, the more delicate shades of brown and warm monochrome being quite indistinguishable. For public exhibitions, even on a large scale, the limelight, skilfully manipulated, is generally to be preferred, whilst for home exhibitions on quite small screens incandescent gas proves an almost ideal illuminant, a recently introduced form called the "Block-light" being particularly suitable. It greatly conduces to the comfort of the audience if the light be completely shut off from the screen when each slide is changed; this may be effected by simply capping the lens, or by using a carrier performing the same function. Finally, let the screen be as nearly on the line of vision of the audience as possible, for nothing is more wearying than having to crane one's neck for upwards of an hour.

**ROYAL Photographic Society.**—The Council have elected the following three members to the Fellowship of the Society:—S. G. Kimber, C. H. Hewitt, and J. Howden Wilkie. Mr. Kimber, of course, is well known as the Secretary of the Southampton Camera Club, and the winner of many medals at the exhibitions. Mr. Hewitt, as chief lecturer on photography at the Regent Street Polytechnic, is known personally to a wide circle of students, and to a still wider one through his writings in the Press. Mr. Wilkie is the photographer in the Solar Physics Laboratory.

## New Books.

"Photographischer Almanach, 1907." Edited by Hans Sporn. 132 pp., 7½ x 5. Leipzig, M. Eger. 1s.

The above is the twenty-seventh annual issue of the Almanach issued by Messrs. Liesegang, of Düsseldorf. It contains a frontispiece portrait and brief biography of its late editor, Herr Hermann Schnauss, and, as usual, opens its pages with a few contributions on current photographic topics. In one section Herren C. W. Czapek, Hans Schmidt, John Mai, and Drs. Hauberrisser and Namais appear as contributors. A selection of abstracts from the German Press is appended, and is followed by reviews of recent introductions in the way of apparatus and materials. The last pages of the volume are occupied with a list of German photographic societies.

## New Apparatus, &c.

Gardiner's Universal Vignetter. Made by Marion and Co., 22 and 23, Soho Square, London, W.

This apparatus is for the making of vignetted negatives direct at the time of exposure, and apart from the saving of labour which thus results, provides for the production of a number of pleasing vignetted effects by ringing the changes on the "vignetting disc" and the background. The apparatus consists of a circular tube of light metal, dead black inside and japanned on its external surface. The diameter is 8 in., and the length 14 in. The tube is hung to the front of the camera, surrounding the lens, which has not to be altered in any way for use with the vignetter. The tube simply serves as the carrier of the vignetting discs, four of which, two transparent and two opaque, are provided with the apparatus.

As shown in the drawing, the discs travel in the tube from the mouth of the latter to close against the lens hood. The handle of the disc is slipped into the travelling block below the tube, and the distance of the disc from the lens is thus adjusted to a nicety. The semi-transparent discs—matt celluloid with a serrated aperture—are for vignettes against light and medium backgrounds. The opaque discs are for the so-called "dark" or "Egyptian" vignettes. The apparatus calls for little explanation beyond what has been said. In use it may be employed for a variety of effects, and we can imagine that a little experience with it in conjunction with a series of, say, three backgrounds—white, grey, and red—will place the photographer in the position to simplify the means of producing vignetted portraits in number. The price of the vignetter is 25s.

The Combined Portrait and P.O.P. Printing Lamp Apparatus. Made by the Boardman Electrical Patents Company, Limited, 10, Southwark Bridge Road, London, S.E.

Readers of our columns do not need to be reminded of the constantly increasing number of apparatus for portraiture by artificial light which have been brought upon the market within the last

year or two. That a number of firms are catering for the wants of photographers in this respect is sufficient proof that the want is a very real one, and, indeed, the experience of professional photographers, to which our notice is drawn in many ways, convinces us that a steady adoption of artificial light in both the printing room and the studio is taking place among the firms who

Fig. 1.

cater for the lower and middle class trade as well as among those whose customers are drawn from the higher ranks of society. Any and every new introduction in this department of photographic manufacturing is therefore of interest to those who have before them the comparison of the facilities and cost of the various types of apparatus, and from this point of view we readily accepted an in-

Fig. 2

vention from the Boardman Co. to witness a demonstration of a new enclosed-arc lamp which they have placed upon the market at a price which they believe—and with good reason, we think—is, within the means of a photographer in however a small way of business. The lamp, we would say at once, is designed for both portraiture and printing, and our tests of it extended to both these applications. Like all the lamps which the firm has placed on the

market, it is used (for portraiture) solely by reflection, the arrangement of the new lamp being shown in Fig. 1, where the screened arc is turned away from the sitter and the light derived from the cloth-lined reflector hung from the ring. The lamp was worked at the low amperage of 12, and, with a lens working at  $f/6$  and an Imperial "Special Rapid" plate, a fully exposed negative was obtained in one second. The lamp in question comprises a single arc, and is not advanced, of course, for the most ambitious work, yet is fully capable of small groups in addition to bust and full-length portraiture of single sitters. It is supplied for running on 200 or 250 volt circuit with either direct or alternating current.

Turning now to the use of the lamp for printing, the second drawing shows the arrangement. With the screen removed and a double ring fitted to the apparatus, the lamp accommodates thirty-two half-plate printing frames, all of which print simultaneously. The time of exposure, as we found it with a negative which we should call a fair quick printer, such as is usually made for P.O.P. printing, was five minutes, a time which works out to 380 prints per hour without allowance for refilling. Still, our readers can judge from this of the output of prints which is possible with the lamp.

The price of the complete installation is £10 10s. for a single-arc or £12 12s. for a double-arc, and the circular describing this efficient and inexpensive apparatus should be worth the study of all those contemplating artificial lighting in studio or printing room.

## New Materials.

A SPECIAL paint, sold as "Velure," has been sent to us by the makers, Messrs. C. Chancellor and Co., 13, Clerkenwell Road, London, E.C., who manufacture it for general purposes, but who inform us that its particular qualifications for photographic purposes have been brought to their notice by readers of the *BRITISH JOURNAL OF PHOTOGRAPHY*. The paint, we find, to give a very brilliant white coating eminently fitting it for application to the reflecting hoods of arc lamps, inasmuch as it is not liable to crack or blister. The high covering power of the paint makes it go far in use, and it might well be kept at hand in the dark-room for other purposes, such as repairing dishes, the enamel on which has cracked. It can also be applied to woodwork. The makers claim great resistant properties for "Velure," fitting it for all purposes where it could be exposed to weather and other severe conditions. The paint is not of the quick-drying variety—about twelve to sixteen hours should be allowed for it to harden—but the elasticity of the coating should compensate for the delay in this respect. The paint is sold in pints, quarts, half-gallons, and gallons, and is obtainable also in a number of colours.

**PHOTOGRAPHIC Society of Ceylon.**—In further reference to our note of November 17, as to the establishment of a society at Colombo, it may now be stated that the headquarters are the Ferguson Memorial Hall, where facilities are provided for exhibitions and meetings. Dr. Andreas Neil, Victoria Memorial Eye Hospital, Colombo, is the Secretary of the A.P.S.C., and will gladly welcome visitors in the island to its assemblies.

**THE Decay of Illustration.**—"The hack illustrator of to-day" (the "Academy" thinks) "seems to adopt the camera as his standard of truth, and to endeavour to obtain with his Indian ink an effect resembling as nearly as possible the reproduction of a photograph. Instead of trying to decorate a page, the hack illustrator would persuade us that he has 'snap-shotted' some scene or incident described by his author." Illustrated journalism has been degraded and deprived of all artistic interest by the wholesale employment of photographs instead of drawings, but the evil influence of the camera has not ended here, since the degeneration is spreading from the journals and their readers to the artists who engage in unwise competition against the photograph. The dull uniformity of our sixpenny illustrated monthlies and weeklies, brought about by their publication of similar and often identical photographs, is now matched by the monotonous impersonality of the wash-drawings by the few illustrators for whom employment is still found."

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, JANUARY 18.

Sutton Photographic Club. Members' Lantern Slides.  
West London Photographic Society. "After-Treatment of Negative for Pictorial Purposes." J. Brown  
Gloucestershire Photographic Society. "Westminster Abbey." E. W. Harvey  
Piper.  
Cowes (Isle of Wight) Camera Club. "Rotary Photographic Papers."

MONDAY, JANUARY 21.

Lancaster Photographic Society. "The Eye, the Human Camera." Dr. W. H. Coupland.  
Southampton Camera Club. Lecture Competition.  
Preston Camera Club. "Picture Making in Holland." A. W. Cooper.  
Leek Photographic Society. Social Evening.  
Stafford Photographic Society. "The Photographic Lens." Goetz Lecture.  
South London Photographic Society. "Ozobrome." T. Manly.  
Catford and Forest Hill Photographic Society. "A New Pigment Paper." M. A. Buthnot.  
Bowes Park Photographic Society. General Meeting.  
Borlase Camera Club (Car-Isle). "Rotary Photographic Papers."

TUESDAY, JANUARY 22.

Royal Photographic Society. "Daguerreotype." Demonstrated. Thomas Rolas, F.I.C., F.C.S.  
Sheffield Photographic Society. "Ely Cathedral." A. Bailey.  
Manchester Amateur Photographic Society. "Rajar" Specialties." C. F. S. Kothwell.  
Hackney Photographic Society. "Holland Revisited." E. T. Coombes.  
Worthing Camera Club. "Tabloid" Brand Photographic Chemicals.  
Darlington Camera Club. "Notes from the Almanac." H. L. Thomson.  
Blyth and District Camera Club. Federation Prize Lantern Slides.  
Leeds Photographic Society. "Ordinary and Orthochromatic Plates." J. W. (Charles) Worth.  
Wallington Camera Club. "Gaslight and Bromide Papers and Lantern Slides." A. H. Dunning.  
Hove Camera Club. Open Night.  
Burton-on-Trent Natural History and Archaeological Society. "Flower and Fruit Studies." Illustrated. J. Seymour.  
Glasgow Southern Photographic Association. "Enlarged Negatives on 'Rotograph' Negative Paper."

WEDNESDAY, JANUARY 23.

Bristol Photographic Club. "Lantern Slide Making." G. Easonsmith.  
St. Peter's L. and A. Society. "Latest Kodak Productions."  
Evesham Camera Club. "Celverux" Shutter." E. and J. Beck.  
Croydon Camera Club. Annual Meeting.  
Ipswich Camera Club. "Our Chapter Houses." E. W. Harvey Piper.  
Borough Polytechnic Photographic Society. "Bromide Printing and Toning." A. J. Bulloch.  
Hampstead Scientific Society. "Enlarging." Demonstrated. R. W. Wylie, M.A.  
Leicester and Leicestershire Photographic Society. "The English Lake District."  
Birmingham Photographic Society. "Intensification and Reduction of Negatives." Frederic Lewis.  
Central Technical College Photographic Society. "The Theory and Practice of Self-Toning Papers." A. W. G. een.  
North Middlesex Photographic Society. "Platinochrom Paper." O. Sichel & Co.  
Worcestershire Camera Club. "What Can be Done with a Hand Camera." C. P. Goetz.  
Dennistown Amateur Photographic Society. "Enlarged Negatives on 'Rotograph' Negative Paper."

THURSDAY, JANUARY 24.

Liverpool Amateur Photographic Association. "Modern Views on Photo-Chemistry." Prof. T. G. Donnan.  
L.C.C. School of Photo-Engraving. "Ferric and Heliographic Processes" B. J. Hall.  
Handsworth Photographic Society. "Photographic Shutters." E. G. Collins.  
Hull Photographic Society. "Photographic Defects and Failures." W. S. Parrish.  
L.C.C. Staff Camera Club. Royal Photographic Society's Prize Slides.  
Rugby Photographic Society. Members' Night.  
Richmond Camera Club. Affiliation Competition Slides.  
Nottingham Camera Club. "Enlarging Simplified." John J. Griffin & Sons.  
Glasgow Eastern Amateur Association. "Enlarged Negatives on 'Rotograph' Negative Paper."  
Workshop Photographic Society. "Stereoscopic Photography." C. P. Goetz.  
London and Provincial Photographic Association. Open Night.

### ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held January 15, Mr. J. C. S. Mummery in the chair. Mr. Louis J. Steele delivered a lecture on "The Beauties of the Higher Alps," in which he described very graphically a number of ascents made of Mont Blanc and surrounding peaks. The lecturer illustrated his descriptions with a large number of lantern slides showing the incidents of mountaineering, and giving a vivid impression of the beauties of the Alpine glaciers and snow-fields. A crowded audience testified its appreciation of the lecturer's photography by frequent applause, and a hearty vote of thanks to Mr. Steele brought to a conclusion a most enjoyable lantern evening.

**SOUTHAMPTON CAMERA CLUB.** The members of the above enjoyed on Monday evening the annual visit of Mr. S. W. Harvey Piper, and listened with the utmost pleasure to his lecture, "Memories of a Mighty Marshland Minster." Mr. Piper's knowledge of all the

great buildings in the land is simply phenomenal, and his description of Ely and its beauties was a flow of architectural lore and deep-seated feeling and sentiment. The lecturer began with the historical connection of the Saxon Princess Etheldreda, and told how she founded the double monastery which preceded the present Minster. After narrating how the riches and lands came to the monks, the early stages of the evolution of the beautiful building were reached, and the portion of the building which was the work of Abbot Simeon, dating from 1080, was shown on the screen. With the history of the sacred pile the enthusiasm of the lecturer grew upon the audience, and a progress of the exterior of the building was begun in which the labours of the successive giants of the architectural periods were described. Upon two of the wonderful architects the lecturer lavished his enthusiasm, first coming Hugh de Northwold, who, with great boldness, pulled down the Norman church, and replaced it with the magnificent one of nine bays, the lecturer's dictum being that Northwold's work was equal to anything to be seen in England. Following him came Alan de Walsingham, whose mighty genius produced work the beauty and solidity of which was beyond compare. The lecturer related how out of the calamity which befell the building in the fall of the Norman Tower the master hand created the opportunity of rearing the wonderful octagon, and surmounted it with the perfectly constructed lantern, whose oaken, lead-cased structure has stood for 500 years. He pointed out the wonderful artistic result of the lighting produced by this structure, and showed by many fine illustrations the almost fairy-like effect of the sombre shade and brilliant lighting. Mr. Piper's description of the details of the architecture, his familiarity with the legends of the cathedral, and his subtle, yet always reverent, references to the old habitants of the Minster, kept his audience in silent enjoyment for a couple of hours, which were all too short, and at the conclusion of the lecture the hearty acknowledgment of the members was quite unmistakable.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION. On Thursday, last week, the Rev. Father Segreaves, of Stonyhurst, lectured on "The Amateur Photographer and the Professional Astronomer." The lecturer prefaced his remarks by a tribute to the amateur photographer, without whose enthusiasm, he said, the plate-maker would not have improved the sensitiveness of his plates and thus made it possible for the astronomer to obtain records of the more distant stars. Father Segreaves showed a large number of very beautiful celestial photographs, many of them taken by himself, as well as a number of most interesting spectroscopic slides of various stars. The lecture was given in a delightful manner, and was followed with intense interest. The description of the nebula in various constellations was very lucid, and the spectroscopic analysis of the same added much to the knowledge of the audience. A very hearty vote of thanks was accorded, on the motion of Dr. Thurstan Holland, seconded by Mr. J. Petree.

CROYDON CAMERA CLUB.—The theory and practice of self-toning papers, with special reference to "Goldona," the self-toning paper of Messrs. J. J. Griffin and Sons, was dealt with by Mr. Green on the 9th inst. So far as the practice went, the lecturer ably demonstrated its simplicity and ease of working, and proved the paper to be a fine example of its class. Its keeping properties are great, and provided the worker takes care to observe three main points, viz., not to underprint, not to use the hypo bath too weak, and not to allow the prints to remain therein for an unnecessary length of time, satisfactory results will follow as a matter of course. As regards the "theory" advanced by Mr. Green, this, to put it mildly, did not meet with universal acceptance, a fact which did not in the least depreciate from the merits of the paper.

THE death of a photographer named John Dodd, of Pride Street, Dublin, took place on January 7.

THE Charles Urban Trading Company, whose cinematographic entertainment competes with that of the famous Zancigs nightly at the Alhambra Theatre, has just issued circulars of about a dozen new films, among which is one of the sensational mountain climbing of Mr. F. Ormiston Smith in the Dolomites. The circulars may be had from the Company at 48, Rupert Street, Shaftesbury Avenue, London, W.

## News and Notes.

ROYAL PHOTOGRAPHIC SOCIETY.—We regret to learn that General Waterhouse finds it impossible to accept nomination this year for the Presidency of the Society. The following extract from his letter to the Council will be of interest to our readers:—"As I understand that several members of the Society are anxious to know whether I will accept nomination for the presidency of the R.P.S., for a third year, I regret exceedingly that it is quite impossible for me to do so. My health has not been good for the last three or four years, and after my recent breakdown I have been advised that I must give up the work I have been doing in connection with the Society and other institutions, and I feel that I have no alternative. I very highly appreciate the compliment of this desire on the part of the members that I should continue as President, and very heartily thank the members and my colleagues on the Council for the help they have always given me in carrying on the Society's work. I hope, if my health improves, to be able later on to take some small part in the work again, but for the present I am quite unable to." We sincerely hope that a period of rest and change will speedily restore General Waterhouse to his usual health, and that, at no very distant date, we may be able to announce his return to active work.

THE Imperial Dry Plate Company, Cricklewood, asks us to say that their recent booklet, "Faults in Negatives," is sent free on receipt of a postcard. They do not ask applicants to send postage.

H. BOWN, LTD.—Mr. H. Bown, of 100, Evelyn Street, Deptford, S.E., writes stating that he is in no way connected with the above business, the conversion of which into a limited company was announced in our columns on January 4.

THE Photo-Secession.—The little galleries of the Photo-Secession (New York) have been occupied for the past fortnight by a collection of drawings in black and white and colour by Miss Pamela Coleman Smith.

HERR PAUL RUE, who succeeded the late Ludwig Schrank as Editor of the "Photographische Korrespondenz," resigned his post on the 31st ult.

MESSRS. DAWBARN AND WARD ask to be allowed to correct the price of a Handbook of Illustration given by us last week at 1s. It should be 1s. 6d. or 5s.

A CORRECTION.—Mr. W. F. Oliver, whose article in the recent "American Annual" we quoted in a review which appeared in our issue of December 7 last, writes to us from Baldwinville, Mass., U.S.A., accusing us of deliberately misrepresenting him. We fear Mr. Oliver has as low an opinion of our discretion as of our conscience if he thinks that we should go out of our way to insult a man whom we had never heard of and against whom we had not the faintest grudge. It appears that when Mr. Oliver wrote of Hurter and Driffield's work as "high-flown nonsensical theories," he was indulging a vein of fine sarcasm directed against those of the American public who had not appraised Messrs. Hurter and Driffield's work at its true value. Mr. Oliver angrily tells us that his meaning was clear enough for any one but a journalist "mentally deficient by misfortune of birth or the decay of senility to understand." This may or may not be the case, but we will only express our inability—we suppose we must be half-witted or in our dotage, as Mr. Oliver kindly suggests—to comply with the request, which we quote *verbatim* and *literatim* from his letter: "If you do not represent something I never anticipated would be connected with the name of photography, I shall expect you to correct the false representations you have made, in the columns of your journal. I shall further expect to receive a copy containing the same."

DIFFRACTION GRATING REPLICAS.—According to a paper by Professor R. W. Wood, in the "Philosophical Magazine" (No. 12, 1906), imperfectly ruled glass diffraction grating can be much improved by immersion for one or two minutes in a 1 per cent. hydrofluoric acid solution, the back of the glass being covered with paraffin wax to prevent the development of latent scratches.

A PHOTOGRAPH has been the cause of a curious situation in Dulcigno, on the Montenegrin territory. The recent formal and

public engagement between the daughter of the parish priest of Dulcigno and the son of a neighbouring cleric was followed by the suggestion that a photograph of the happy pair should be taken. In all Dulcigno there was no photographic studio, therefore a photographer was summoned to the spot, and, as it commenced to rain, to the interior of the church, where the photograph was taken. The artist placed them in front of the altar, with the old Byzantine pictures of the Saints behind them. The result of his artistic efforts was extraordinary. The bride appeared in the arms of the stern-looking Byzantine Madonna, while the bridegroom had completely concealed the great figure of St. John the Baptist, taking the saint's golden aureole around his own head. The jealous girls of Dulcigno, and the still more jealous young men of that sweet town, however, pronounced it an insult to the saints and a desecration of the church. They succeeded in deciding the authorities to close the church, and asked the Metropolitan of Montenegro to give satisfaction to the Saints by the punishment of both priests and by the annulment of the engagement of the sweet Dulcinea of Dulcigno with the assumer of Saint John's aureole. All Montenegro is now waiting to see how this peculiar church question is to be solved.

**Tin Supply of Platinum.**—The increasing price of platinum is, according to a report by F. W. Horton, in the U.S. "Geological Survey Journal," due to the unsettled state of affairs in Russia, which is the principal platinum-producing country. The chief districts where the metal is found is on the banks of the Iss, Vija, and the Upper Tura, in the Tagil and the valleys of Eastern European Russia, although it appears to be scattered about in different districts in small quantities. Generally, it occurs in a special silicious sand in the form of minute grains or larger lumps, and this sand varies in thickness of layers of from 10 in. to 100 in., and is frequently covered by about 50 ft. of ordinary sand. The method of extraction is comparatively primitive, and consists of washing away the lighter particles, collecting the heavier ones, and then separating the platinum by hand picking. Since the beginning of 1905 the U.S. Geological Survey has examined the so-called black sands from all parts of the United States, and the precious metal seems to be fairly general in occurrence in California and the Western States, and less so in a few of the Eastern. Generally it occurs with gold, and British Columbia is the second largest producer, whilst small quantities are also found in Canada and on the Yukon. Very small traces have been found in Brazil, in Spain, New South Wales, Burmah, Japan, Borneo, New Zealand, Tasmania, Sumatra, Honduras, Ecuador, and French Guiana. Where it occurs with gold it is collected by the usual concentration process, and the concentrates treated with a sodium amalgam to separate the gold, and then treated with a hand magnet or "by blowing in a pan or horn spoon" to remove lighter particles. Researches are in progress to find an economical method for concentrating the ores and extracting the metal, but the outlook so far is not rosy, and as high, if not higher, prices will obtain.

**Royal Photographic Society.**—We are pleased to announce that Mr. E. Sanger Shepherd has been awarded the "Progress" medal for his researches and inventions in connection with the three-colour process.

An international exhibition dealing with printing, photo-mechanical reproduction, and bookbinding is to be held in Paris in the Grand Palais des Champs Elysees from July to October. The exhibition, which is held under Government warrant, is to have the support of the Ministry of Public Instruction and of Commerce and Industry, and we understand that large allocations of space have already been made to exhibitors under one or other of the chief sub-sections of the exhibition. A feature of the exhibits is to be the actual demonstration of processes such as magazine printing, half-tone block-making, and bookbinding. There is a prospect of a daily newspaper being produced in the exhibition instead of in its usual offices, and from the preliminary information available there seems no doubt that every effort has been made to make the collection of the greatest interest to the printing crafts, and that the overtures of the organisers are meeting with a liberal response from the trade. The organising managers in Great Britain are Messrs. Frederick T. Corbett and Frank Colebrook, both well known to our readers as contributors to our columns. The conditions and charges for exhibition are obtainable from these gentlemen on application to Nos. 2, 3, and 4, Cheapside, London, E.C.

## Correspondence.

\*.\* *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

\*.\* *We do not undertake responsibility for the opinions expressed by our correspondents.*

### PLATES FOR STEREOSCOPIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—The importance of the 15 x 10 cm. size of plate for stereos, and postcards appears to be realised on the Continent, if not in England. Mr. Jahr, of Dresden, writes me:—"You will see that I have listed the size 10 x 15 cm. I have read your pleading for the 10 x 15 size in this year's 'B.J. Almanac,' and (you?) will perhaps be interested that in to-day's 'Photograph' (Bunzlau, Jan. 8, 1907) the same size is warmly recommended as the most practical for pocket cameras, by Mr. J. Christoph." Makers of apparatus would do well to abandon the 5 x 4 size, and in all new work adopt the 15 x 10 cm. (5 1/2 in. x 3 15/16 in.).—I am, yours faithfully,

CHAS. LOUIS HETT.

Springfield, Brigg,

January 14, 1907.

### THE LATE MR. J. T. SANDELL.

To the Editors.

Gentlemen,—We feel sure you will gladly allow us, through the columns of your paper, to tender the most sincere thanks of Mrs. Sandell and her family to yourself and to your readers for the hearty support accorded to our appeal on behalf of the late Mr. J. Sandell. The amount reached was £257 15s. 8d. It was his great desire before he passed away that he should be allowed to express his gratitude to all concerned.

May we add that Mrs. Sandell is left with a family of eight, and that the money in hand, together with any further subscriptions which may be received, will be devoted to the assistance of Mrs. Sandell and her children in such a way that they may make a fresh start.

We ourselves would also like to assure you of our hearty thanks for the great service that you have rendered to the fund by your assistance and support.—We are, dear Sir, yours faithfully,

J. B. B. WELLINGTON,

THOS. K. GRANT

January 10, 1907

### THE PYRO-AMMONIA DEVELOPER.

To the Editors.

Gentlemen,—Though I said I did not want any discussion in regard to pyro-ammonia developer, which would carry us probably very far, allow me please only a few answers to your assertions in answer to my letter.

Firstly.—I do not think I use an ammonia solution of very uncertain strength. I use strongest ammonia solution in a certain quantity of water, and always the same.

Secondly.—I did not compare pyro-ammonia with pyro-soda, and if the first oxidises, when mixed, it does not do so to any perceptible extent before the fourth or fifth plate has been developed in it.

Thirdly.—Of course, any one is at liberty to use a fresh quantity of developer for each plate when using pyro-ammonia, but the same can be toned with any other developer, yet it need not be. This would be specially troublesome if one had as many as 800 plates, 8 x 10 inches, to develop after a trip, as I had.

Fourthly.—For prolonged development (by which I mean slow development) experiences might differ. It proved satisfactory to me.

Fifthly.—As to my experiences with first plates coming up more slowly than subsequent ones, I had eyes to follow development and stopped it when sufficient. Exposures differing somewhat had also something to do with this perhaps, and I never thought to blame the uncertainty of the developer for this.

Sixthly.—My first dose of ammonia was the only one, and I had hardly ever to add additional, and only when I thought of adding a fifth or sixth plate, and then only to finish it, getting impatient if it took over from 5 to 10 minutes for completion.

I wish now to add one more word. I have no interest in praising or

pushing the pyro-ammonia whatever, and I leave every one at liberty to use any developer he chooses, but after many years' experience I think that much better and more uniform results can be obtained when using all along one developer you are familiar with, than changing with every new one put on the market. The same applies to plates.—Yours very truly,

A. LEVY.

[As M. Levy expresses a wish not to enter into further discussion of the subject it is not for us to comment further on the points which have been raised. We hope to refer before long to the pyro-soda developer when it may be convenient to deal with one or two of the points on which we are in disagreement with our correspondent.—Eds. B.J.]

## Commercial & Legal Intelligence.

**A "WANTED" Photographer.**—At St. Helens Police Court, last week, Wm. H. Greenway, a photographer, of Leeds, was committed to the Quarter Sessions on a charge of stealing—as bailee—a camera and other photographic articles, valued £8, and also with embezzling £1 11s. 6d., the property of William H. Campbell, a St. Helens photographer. Evidence was given that prisoner entered the prosecutor's employ in 1905, but he absconded with the money and articles. The police searched for him, but nothing was heard of him until he was committed to prison at the Leeds Quarter Sessions. Prisoner was brought from gaol in company of two warders to attend the court, and the chief constable told the bench that he was wanted by some twenty police forces in the country.

**An Inventor of Metallic Prints.**—At the Salford Bankruptcy Court, on January 8, before Mr. Registrar Forrester Addie, Frederick Ahrie, now living at Moss Side, and previously in London, was examined by the Official Receiver (Mr. J. Grant Gibson) as to the causes of his failure. The debtor, it was said, is a German subject who has been trying for several years to perfect an invention for the manufacture of sensitised papers and plaques for photographic work. Much money has been spent, but he told the court there had been very little return. He was at one time associated with a limited company, and later he had another business, but through a variety of causes he had been unable to make headway, and he is now manager for a local company. The examination was closed.

**EAST END BANKRUPTCY.**—At the London Bankruptcy Court last week the public examination was held of John Edward Reeves, photographer, 50, Hermit Road, Canning Town, E., before Mr. Registrar Brougham. The statement of affairs filed by the debtor disclosed gross liabilities amounting to £786 0s. 8d., of which £197 14s. 6d. was due to unsecured creditors, to fully-secured creditors £588 6s. 2d., the value of the securities being returned at £600. The assets were returned at £54 3s. 10d., thus showing a deficiency of £143 10s. 8d. The whole of his unsecured liabilities were in respect of goods supplied. The fully-secured creditors held mortgages on the freehold of Mersea House, 109, Queen's Road, Lowestoft, and the lease of 48 and 50, Hermit Road, Canning Town, also second charges on those properties to secure an advance of £225, made on May 9, 1906. The household furniture belonged to his wife. He had never kept proper books of account, so that he could not now show how he stood at any particular time, but he always knew how he stood. He admitted that it was usual to keep books in a business like that carried on by him.

We would remind intending exhibitors that January 26 is the latest date for entries for the "Midlands trio" of exhibitions—Sheffield, Nottingham, and Leicester.

A COURSE of twelve lectures and demonstrations in various branches of photography will be given by Mr. Charles W. Coe at the Cripplegate Institute, Golden Lane, E.C., on Friday evenings, at 7.15, beginning January 18. These lectures, which are of a thoroughly practical character, are open to both ladies and gentlemen, the fee for the course being only 12s., and including the free use of dark room, apparatus, and chemicals. Tickets are now ready, which, together with syllabus and full particulars, may be obtained from the clerk's office at the Institute.

## Answers to Correspondents.

- \**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C."* Inattention to this ensures delay.
- \**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*
- \**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

May Bone, Norfolk Studio, Norwich Road, Fakenham. *Photograph of a Royal Motor Mail Van Outside Fakenham Post Office.*  
 W. H. Warburton, Harris Promenade, Douglas, Isle of Man. *Photograph of the Douglas Choral Union in the Opera "Paul Jones" on the Stage of the Gaiety Theatre, Douglas.*  
 H. T. Cave, 3, Church Street, Dereham, Norfolk. *Photograph of Dereham Motor Mail Vans and Post Office.*  
 F. Deakin, 121, Snargate Street, Dover. *Photograph of a Birdseye View of the Old Channell Tunnel Works, Dover.*  
 E. Abrahams, 116, Station Street, Burton-on-Trent. *Two Photographs of the King and Queen in Group with Lord and Lady Burton, &c.*

- S. B.—1. "Practical collotype," by A. W. Fithian C. Iliffe, 2s. 6d.  
 2. The lens is very suitable for groups.
- F. B. (Miss).—We should not advise you to take the responsibilities of a business of your own unless you can do so with an assurance of support from those in your neighbourhood. Without any special reasons for going into the business, we sincerely think you will be exposing yourself to the possibility of losing money. Of course, we know nothing of your business training, but as you make no mention of it we advise you as above.
- NETHERBY.—The print is evidently on one of the collodion papers toned with gold only most probably. As your dealer to supply a collodion paper of the rough surface, or write to one or other of the manufacturing firms whose announcements you will see in our pages.

**SULPRIDE TONING.**—Will you kindly tell me why it is necessary to dry the bromide prints before toning to sepia in the ferricyanide and sulphide baths, as I find I get a much better tone if the prints are treated immediately after the hypo has been eliminated and before drying the prints? I shall be glad to know if I may safely continue to tone without drying prints first.—PERPLEXED.

It is not absolutely necessary to dry the prints prior to toning. **PHOTOGRAPHS ON TUMBLERS.**—I have just returned from the Continent, and whilst there saw a method of photography on glass. It is as follows: A person can have their photograph produced on a drinking glass (an ordinary tumbler) either from a direct sitting (the photograph in this case being taken just in the ordinary way), or it can be obtained from an old photograph, so that the images of present or absent persons can be produced on the drinking glass. An interval of one or two hours elapses between having the finished glass and first going to the photographer. As far as I can see, it is not a film transferred on the glass. It is a true positive negative, and in every way equal to an ordinary photograph. My object in addressing you is to ask you to kindly let me know if you have ever heard of anyone having a process for obtaining photographs of persons on drinking glasses?—GUSTAV DUFT.

Unless we saw one of the drinking glasses, or had fuller particulars than are supplied in your communication, we can give no definite opinion as to how the pictures are made upon them. As you say there is no appearance of a transferred film, we can only surmise that the pictures are photo-enamels—that is, the image is produced in ceramic colours, and then "fired" into the glass. If that is the method employed, and we suspect it may be, we scarcely see how the results are obtained (commercially) in the brief time you mention.

**J. BUSH.**—If the lens is a doublet or rectilinear, as we assume it to be from the drawings, there is no difference in the illumination in the two cases. The only difference is in the distances of the pieces of apparatus from each other, but this will not in any way affect the good working of the enlarger so long as a sharp focus is obtained.

**E. J. K.**—The "Optician" or the "Optical Trade Journal." There is no exact equivalent. The best optical papers are in German.

**INTRODUCING BACKGROUND, ETC.**—1. An amateur negative-portrait, with part of hat cut off, has been brought to me to make another negative with the hat complete. I propose blocking out all the background (as it is a wall), printing on to a large piece of P.O.P., painting in the top part of hat, and then copy. Is this as good a plan as any? If so, what paint for the hat—a neutral tint water colour? Could a sketchy background of trees, etc., be painted in at the same time and with the same colour? 2. A studio just erected faces east, not troubled with sun now, but shall be, so think of putting paper on the glass inside. What is the best paper to use, and how applied, or is there a better material?—**WEEDEE.**

1. The plan you suggest will be quite correct, but instead of making the print on glossy P.O.P., we should recommend you to use a matt paper. You will find that will take the colour much better than the glossy, and show less hand work in the reproduction. A light sketchy background will much improve the effect. For the colour use one that matches that of the print as nearly as possible. 2. White tissue paper, which may be attached to the sash bars with gum or starch. Better than paper would be thin tracing linen stretched on light wooden frames, which may be slid backward or forward as required, or removed altogether when not wanted.

**SPOTS ON C.C. PRINTS.**—Will you kindly inform us as to the cause of the black spots on the enclosed C.C. prints? They are not to be seen after toning, but after the fixing. We keep a tin scoop in the hypo tub. Do you think the rust from same will cause these spots? The prints were toned with—

Chalk .....	1/2 oz.
Gold .....	1 gr.
Water .....	2 oz.

which is made up twenty-four hours before using.—**V. AND P.**

Metallic particles are the most usual cause of these spots, but they are most active on the untuned prints. We do not think particles of rust in the hypo would account for them. The most common cause is the use of zinc shavings for cutting circular and oval prints, minute particles of zinc falling on the paper before toning.

**GUM BICHROMATE PROCESS.**—I have been trying to coat paper for gum-bichromate printing. I do not have very much difficulty in getting an even coating, but I am troubled with innumerable white spots, which appear after the coating is laid on. This seems to be particularly the case with well-sized papers—in fact, I have used several kinds of paper recommended in hand-book on gum-bichromate; and I have tried gelatine, flour paste, and fish glue for sizing, but find the same difficulty. I will be very pleased if you will suggest a remedy for this spotting; and I would also like to know if the trouble is a usual one.—**GUM.**

As the spots occur with various colloids, it is clear that the fault lies in the manipulation, and is probably due to air bells, either in the colloid itself or caused during the coating. They are particularly liable to occur if the coating is applied with a brush, which causes frothing. One remedy is to damp the paper first, and another to apply the pigmented colloid with a roller and then even the coating out by working gently with a badger-hair softener.

**IMOGEN-SULPHITE.**—1. What is the chemical composition of imogen-sulphite? 2. How long will the powder keep in good condition? 3. Will brown tones obtained on a "chloride" paper by development with a diluted solution be permanent? 4. Is washing necessary between development and fixing?—**IMOGEN.**

1. A proprietary article, the composition of which is not stated. 2. We should say a year at least in a dry place and in a sealed tin. 3. Yes. 4. It is not absolutely necessary, but advisable with this as with every other developer.

**W. ROBERTS.**—We cannot say without seeing the negatives.

**STRIPPING P.O.P.**—Could you give us the amount of turpentine and beeswax to make up a solution to put on ferrotype plates for stripping P.O.P. prints?—**L. AND S.**

Beeswax .....	20grs.
Turpentine .....	1 oz.

**COPYRIGHT AND COPYING.**—1. For the purposes of a postcard I want to copy a litho print bearing the date 1840. The print is not stated to be copyright. Should I be running much risk in copying; and if the author is still living, what penalty should I be liable to? 2. The print is in black ink, but has a yellow tinge. What kind of plate would serve best?—**POSTCARD.**

1. Copyright lasts seven years after the death of the author. The penalties may be £10 for each copy made. We should say that more likely than not the copyright has expired. 2. An orthochromatic plate and yellow screen.

**H. J. W.**—There is a list in the "Almanac," p. 555 to 586 of the 1907 volume.

**C. M. AND CO. (Watford).**—**E. W. Foxlee**, 22, Goldsmith Road, Acton, W.

**COPYRIGHT.**—I took a good view with difficulty from a church tower to sell as picture postcards at 2d. each. I now discover a local stationer has had it copied and selling at 1d., without permission or payment. I did not copyright the view. Can I do anything in the matter to prevent him or anyone selling the same?—**A. E. T.**

No, you cannot take any action for infringement before registration. Your best course is to register the copyright now, and you can prevent further sales of the postcard.

**COPYRIGHT.**—Your opinion on the following question of copyright would be esteemed: We have photographed a local clergyman by invitation and without payment, and presented him with copies. The picture was registered in the usual way two years ago. It is now published in a local year-book without our permission and without our name—in fact, another name substituted. When registering, the clergyman was asked and gave his permission verbally that we were to retain the copyright, and if anyone wished to reproduce it they were to be referred to us. We have not a written assignment from the sitter. Have we good cause of action for infringement?—**J. W. D'ANTER.**

Certainly you have. Your sitter cannot prove that you received a good or valuable consideration for the work, and as you have not the copyright is yours.

**WORKING-UP.**—Can you oblige me by advising me how to obtain a knowledge of working-up B. and W.?—I am an assistant photographer, and it is a branch of my work I know nothing about, except enlarging on bromide. Can you advise me of a book which will give me construction on the finishing of B. and W.?—**ASSISTANT.**

The only book on the subject is "Retouching Negatives and Prints," by R. Johnson, published by Marion and Co., Soho Square, London, W.C. Postal lessons, which you will see announced in our advertisement pages, should be of service to you.

**SENSITISED TRACING PAPER.**—Could you kindly inform me of any simple method whereby I could coat and sensitise tracing paper so that I could produce a paper negative from a coarse black and white tracing by contact.—**PHOTO-MECHANIC.**

You require to sensitise with the "sepia" iron formula used for commercial papers, but you will find a difficulty in getting any watery solution to "take" on tracing paper. A more suitable material is Linaura, a semi-transparent fabric sold by Reeves and Co., Farringdon Avenue, E.C. You will find a formula for the sensitiser on p. 992 of the "Almanac."

**STUDIO.**—I should be greatly obliged if you would advise me on the following: 1. I have a studio 20ft. by 10ft., with 10ft. of glass along roof and side, which faces north-east. A high wall stands up 5ft. away from the side glass (a cemented wall). I want to know what colour blinds or curtains to have (most suitable), and whether running along on rings or wire would answer, or not. 2. Is it necessary to stipple or whiten the glass? 3. I have also a 12 by 12 studio camera. I would like your opinion of a lens focus, etc., suitable (or lenses). I want to do cabinet full-lengths and busts. also C.D.V.—**READER.**

1. We should advise you to use buff curtain festooned on a pair of parallel wires along the roof. 2. We judge that you can

dispense with it. 3. For a cabinet full-length you will be able to afford about 15ft. between the camera and the background, which will permit of a 14in. lens. We should say a 12in. or 14in. portrait lens would answer your purpose. It will not allow of full-length carte figures, but this, we take it, you do not require.

**ARTIFICIAL LIGHT.**—I believe there are many photographers who would like to introduce electric light into their studio if they could only be convinced that the results to be obtained will compare favourably with good daylight pictures. I am one of these, and as the introduction of electric light would mean expensive alterations in my studio, before taking the step I ask your advice. 1. Can full-length portraits and groups (that will honestly compare with good daylight pictures) be taken by a single electric lamp? 2. With gas and flash light work I find that dark objects photograph much darker than they would if taken by daylight, and there is always absence of detail in the shadows. Would the results of electric light be the same? 3. If I had my studio altered to the long slant-roof principle, and carried it up to 14ft., would that be of sufficient height? 4. Can you recommend a lamp both for printing and taking which is not much trouble—exposure about 3 seconds,  $f/6$ , alternative current, 100 volts—and approximate cost of same?—R. A.

1. Portraits can be produced by electric light equal to daylight work, provided the light is properly used. Full-length portraits and groups of two or three figures may be taken with a single lamp if of sufficient power, but groups of several figures are more difficult to manage. See our leading article published during December, 1906, on this point. 2. Your heavy shadows with gas and flash light are due to under-exposure and unsuitable distribution of the light. They should not occur with properly-managed electric light. 3. Yes, a lamp could be fitted in a studio altered as you suggest, but, if possible, the height of the roof should be rather more than 14ft. 4. A Westminster should answer your purpose, but you will only get a very short arc on a 100-volt current. When ordering you must specify the voltage and that it is an alternating current, and your wiring should be arranged for 10 to 12 amperes.

**FLAMING ARCS.**—I have just read with great interest the article in the current number of the *BRITISH JOURNAL OF PHOTOGRAPHY* on "The Use of the Flaming Sunlight Arcs in Portraiture," and in connection therewith should be obliged if you would give me the following information. 1. Do professional photographers touch out all the "small-pox" marks in Z and P, p. 20, or how do they get rid of them—touching out on such a large scale would surely be such an arduous task that a photographer would never have finished? 2. Can you tell me the name of a really good book from which to learn something of the art of portraiture, also name of publisher and price?—**PORTRAITURE.**

1. Professionals touch out all the freckle marks in portrait negatives, using a lead pencil for the purpose. With large negatives the work does take a long time, but then soft and broad pencils are employed. The illustrations to which you refer were enlarged about four to five diameters, and the original negatives could be retouched by a smart worker in about twenty minutes. 2. H. P. Robinson's "Studio and What to Do in It," 2s. 6d.; Hewitt's "Practical Professional Photography," 2s. Either may be obtained from Dawbarn and Ward, 6, Farringdon Avenue, E.C.

**NEW STUDIO.**—Do you know of any studio in England built on the "Robinson's studio of the future" plan, and, if so, would you recommend one in accordance with the sketch enclosed? The light is of ground glass 15ft. by 11ft., commences 4ft. from ground, and upright only. No top light from roof, which is slated. The dimensions are 30ft. long by 15ft. wide. The roof slants to back. The studio to face north, there being no buildings nearer than 80ft. Any suggested improvements appreciated, and if you know of any studio erected in this neighbourhood we should be glad to know that we might inspect it.—W. B.

There are a few studios built on the Robinson "Studio of the future" principle, but we cannot say if there are any in your neighbourhood which you could see. We think the design you submit would, if carried out, result in a very suitable building for modern photography. We can suggest no improvement if the vertical light is decided upon, and in this case it appears large

enough to give good illumination even for groups of several figures.

**URANIUM PRINTING.**—On page 7 of B.J. for January 4 you have an article on uranium printing process. In giving formula for sensitising bath, it reads:  $\frac{1}{4}$  oz. nitrate of uranium. Would you mind letting me know if this is correct? It seems such a large amount for such a small bath.—G. V. SIMMONS.

The amount is large, we are aware, but it is correctly quoted from the American paper. The solubility of the uranium nitrate is, however, sufficiently great to enable the bath to be made up. Our own experiments in uranium printing have been made with a 20 per cent. solution as sensitiser, and we suggest that you may find it possible, after trying the full-strength formula, to reduce the proportion of the uranium somewhat.

J. G. T., W. C. T., C. C., and others. In our next.

**A LICENCE FOR PHOTOGRAPHY.**—Will you kindly let me know if it is necessary to have a licence for outdoor photography, as I was stopped by a police-constable last Thursday at Seacombe-cum-Poulton? He asked if I was aware that I required to take out a licence. I have been in the photographic business for about fifteen years, and this is the first time I have been interfered with. My method of working is calling on householders. I ask them if they will stand at the doors, while I take a photograph of them and the house. After that I take round and show them a proof. If they give me an order for any I tell them I will get them ready and finished for the week-end, and they pay on delivery. I do not ask or take any cash down, either at the time I take a photograph of the house or at the time I show them the proofs, but I receive the full amount, or part of it, when they receive the finished pictures. The constable told me it came under the Pedlars' Act; he called it a craft—one travelling from place to place. He said he had a case tried, and the photographer was fined for not having a licence. I wish to state that I do not get a number of pictures finished and take them from door to door asking people to buy them. I only take those round that people give me an order for.—J. WEATHERY

Working on the system you do, we have a very strong opinion that a licence is not required, the assertion of the policeman notwithstanding. The Act 22 and 23 V., c. 36, says. A hawk's licence is not required by the maker or worker of goods who carries them abroad or exposes them for sale. You are the maker of the goods that you afterwards offer for sale. If you are again interfered with, call the attention of the policeman to this clause in the Act. It is the first time such a thing has come under our notice.

**C.C. PAPER.**—How to obtain good blacks on C.C. paper, in place of brown-black.—**PERSEUS.**

Real blacks are only to be obtained on C.C. paper with first toning in gold followed by platinum. Formula for gold bath: Borax 2oz., gold chloride 2gr., water 35 oz. Upon tone obtained in this bath depends resulting colour. Warm chocolate is a rough guide. Wash for ten minutes and tone in: Chloroplatinite of potash 15 gr., phosphoric acid  $\frac{1}{4}$  dr., water 15 oz. Use 3 oz. of this stock diluted to 20 oz. with water. The collodion papers vary with regard to tone obtainable.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Dr. von Rohr reminds photographers of the past and notable work of Mr. R. H. Bow in photographic optics. Mr. Bow celebrates his eightieth birthday on Sunday next. (P. 62.)

The second chapter of a series on "Aerograph Work" deals with the care of the instrument, the use of eraser, and the treatment of various prints. (P. 60.)

Mr. J. C. Strauss, the famous photographer of St. Louis, a selection of whose works is now being shown at the "B.J." Offices, has stated his belief in the renaissance of photographic portraiture. (P. 65.)

The tendencies towards specialisation in a photographic business lead us to discuss the possible directions in which a photographer may be led to improve his business. (P. 59.)

Professional photographers obtaining permission to photograph certain scenes are advised to secure a written statement by which the copyright is specified as theirs. The recent case of Stackemann v. Paton was of a special character, but is apparently being quoted as of general application. (P. 58.)

Some further notes and suggestions on photography for advertising purposes appear on page 65.

Society proceedings of the week have included Mr. P-las on "Daguerreotype" at the R.P.S., and Mr. Manly at the South London "Ozobrome." (P. 71.)

Under "Photo Mechanical Notes" will be found a visual method for checking the distance of the line screen from the ground glass; also a new grain process of Klimsch and Co., Frankfurt. (P. 67.)

Attention has been drawn to the use which may be made of photography in the duplication of historical documents. (Pages 67 and 66.)

Mr. William Gill advises every photographer to study the examples of American professionals now being shown at the "B.J." Offices. (P. 73.)

## EX CATHEDRA.

### A Year of Celebrations.

The article by Dr. von Rohr on another page, drawing attention to the eightieth birthday of Mr. R. H. Bow, is also a reminder of the other celebrations which should take place in 1907 were we as a nation possessed of the same disposition to hero-worship which is evidenced on the Continent by the statues and "denkmals" at the street corners. January 6 was the centenary of the birth of Josef Petzval, the designer of the portrait lens first made by the house of Voigtländer more than fifty years ago. July 26 will mark also the hundredth anniversary of the birth of Niepce de St. Victor, the nephew of Nicéphore Niepce and the originator of many processes in the early years of photography. Then on May 15 exactly fifty years will have elapsed since the awards of the prizes by the Duc de Luynes for permanent photographic prints, a competition in which prizes were gained by Poitevin and Pouncy, from whose combined labours the all popular gum process owes its existence. So far back in history do the latest foibles of the pictorial photographers go for their solemn origin. Yet still one anniversary of remoter date falls for celebration during the present year in the instance of the publication by the Turinese professor, Beccarius, of his researches on the darkening of "horn silver" (silver chloride) in the light. We are also told by our contemporary, "Die Photographische Industrie," to whom these burrowings into the past are as natural as to our late contributor "Historicus," that it is exactly fifty years ago that the first photographic portraits were made in London by gaslight, though we are unable to identify the occasion to which our contemporary refers.

### Photography in Libraries.

The article which appears elsewhere on this subject is, notwithstanding some erroneous statements, well worth careful perusal, on account of the valuable suggestions it contains. It is not the first time that this subject has been brought forward, and the crying need for cheap reproductions pointed out. It is universally acknowledged, too, that photography alone is satisfactory as the copyist—hand transcription must necessarily be not only slower and dearer, but far less reliable. Besides, in many cases, even the most careful artist is utterly incompetent to impart to a copy those delicate details which impart character to an old MSS., and in some cases actually determine the particular period at which it was written. The statement that owners of valuable originals are loth to send them out of their possession for reproduction, and that "hair-raising" cases of damage can be quoted, may well be met on the photographer's side by the fact that he would rather not be entrusted, even for a day, with delicate, costly originals, which may be worth thousands of pounds, and for damage:

to or loss of which he may be held responsible. We have no doubt that the writer of this article is correct in his statements as to the difficulty of obtaining in Germany the necessary materials. We do things better in England, and there is not the slightest difficulty, as we have proved, by personal experience, in obtaining negative paper in daylight loading cartridges. As regards the orthochromatising of the emulsion, whilst this presents no difficulty to the manufacturer who is in the habit of making orthochromatic emulsion, it is not so advantageous to sensitise the negative paper by bathing at home, on account of the absorption of the dye by the paper fibres, but even this would be discharged by an acid fixing bath and subsequent washing, and should a demand arise the manufacturers might supply a colour-sensitive paper.

### Essentials for the Work.

There is not, as the writer suggests, the slightest need for a specially built cheap apparatus if any existing rear-focussing camera is available. There are also numerous tilting tables on the market which are much superior in stability to the ball and socket. But beyond these there is one essential which apparently has been overlooked, and that is the necessary knowledge to enable one to carry out the work efficiently. Rather more is required than the broad fact that to reproduce yellow and faded MSS. correctly an ortho-plate and yellow screen may be required, for many of the old writings are illuminated, and one has to decide what is and what is not required, whether a reproduction should be in correct luminosity of the colours or contrast. For instance, supposing the subject to be reproduced is a book cover (and we are now quoting a case which has actually been laid before use recently), on which are green, bright red, violet, and gold ornaments. Here the use of an orthochromatic plate and a correct luminosity colour filter would give an absolutely erroneous rendering, and a flat monotonous print be the result, but by duly suppressing one or two colours by a filter of the complementary tint a much more satisfactory result will be obtained. Again, even when dealing with MSS. in black, on what was no doubt originally a white or nearly white ground, it must not be overlooked that to the antiquarian and in many cases to the philologist also the tone and texture of the vellum or paper is as valuable as the text itself. These facts merely point to the advantage of working under the eye and direct guidance of the owner of the article and of an intelligent carrying out of his requirements.

### Photographic Libraries.

In our last issue we expressed our grave doubts as to the feasibility of the scheme suggested by M. Goldschmidt, but there is no reason why the duplication of works should not be undertaken on somewhat similar lines to that suggested in the article elsewhere. This naturally raises the question of glass versus paper as the necessary negative material. The latter certainly has the advantages of want of fragility, less room for storage, and possibly cheapness. But if such a scheme is to be carried out it is obvious that for the original negatives, even if one accepts the dictum that the reversal of black and white is immaterial, glass would certainly possess some advantages, not the least of which is the quicker printing. The idea of utilising machine-printed bromides as the process of printing is excellent—for the paper-maker—but except when only a few copies are required, one would naturally hesitate to adopt a process in which the image is of that admittedly uncertain substance, finely divided silver. Although silver images have been known to keep their pristine freshness for many years, one naturally doubts the wisdom of employing the same for producing books, which are at any moment liable

to contact with fingers that cannot be guaranteed as chemically clean or dry, and therefore to add to the above possibly fugitive substance another of a hygroscopic nature such as gelatine would not appear commendable. If but a few copies are required for interchange with other libraries or antiquarians even, one would think that it would be advisable to use a more permanent process such as platinum printing, which offers not the slightest difficulty in reproduction in line.

### Expedients in Extremis.

The editors of our American contemporaries who live lives of ease by filling their pages with British articles, sometimes give us in exchange some priceless gem to more than compensate for all that they have taken. For example, we read in one of the monthlies the following idea, the beauty of which, as Captain Cuttle used to remark, lies in the application. You are in a crowd with your hand-camera, and cannot get a glimpse of the roadway along which the Royal procession will presently pass. The uninspired mortal would give up the job and go home, unless he has been fortunate enough to see the hint in our contemporary, which is to persuade a tall and strong (and good-natured) man to let you sit on his shoulders whilst you sight your subject and expose the plate. This hint should be invaluable to Mr. Tilney. On the other hand, it will rarely be of service to Mr. J. C. Warburg.

### Enterprising Burglars Beware!

We continue to read in the daily newspapers of the triumphs of the camera in unmasking the thief, who from the office safe purloins the deeds and bonds which, as the trusted servant of the firm, he has placed there for safe keeping. It may be our misfortune, but we have never seen one of the actual photographs which these criminals are reported to take of themselves by the very act of opening the safe door—electric release of shutter in concealed camera is the usual story—but we may state our personal knowledge of the means by which a series of petty thefts from an office drawer in a public institution was detected. The drawer was fitted in such a way that a stop-watch placed at the back of it was arrested on its being opened. It was thus found that the thefts took place regularly every morning between 8.30 and 9.15, that is to say, about half an hour before the regular time for the staff to assemble. A morning was then selected for the visit of the thief to be signalled to two persons in the adjoining room, and for this purpose a small alarm clock—we hope Mr. Welborne Piper will find this hint of service—was placed in the drawer, and set to go off on the latter being opened. Events turned out as expected, and the thief was caught red-handed. The comic side of the incident came when he was brought before the principal, from whom the culprit received the following useful hint:—"Young man, you ought to have thought that it would be easy to detect you in this way." We suppose this narrative, every detail of which occurred, is too flat for the newspapers that serve up the marvels of modern photography in paragraphs which have the one great merit that the feats astonish photographers more than anyone else.

### Valuable Consideration.

A case in which the important question as to whether a photographer had or had not received valuable consideration has recently been brought before us by a firm of photographers who have studied the reports of copyright cases in our columns and had approached us to confirm the conclusion to which they had themselves arrived. They had recently approached a gentleman for permission to photograph some scenes illustrating an organisation of which he was

director. The permission had been at once granted, and the photographs forthwith taken. The latter were obviously intended for reproduction in the press, and as proof of the understanding which existed as to the ownership of the copyright, the photographers had an agreement with the director that any articles on his organisation which he might write could be illustrated with their photographs. This agreement the director subsequently sought to annul by claiming the copyright in the photographs, on the ground that the permission given by him was a good consideration, and that therefore the copyrights were his. In support of this view he quoted the case of *Stackemann v. Paton*, reported in our issue of May 4, 1906, the circumstances of which are doubtless in our readers' minds, or if they are not, will be found on page 689 of the current "Almanac."

#### The Lesson of the Stackemann Case.

It may be well, however, to remind those photographers whose business brings them into similar contingencies of the peculiar circumstances of the *Stackemann* case, because the judgment of Mr. Justice Farwell in that suit is evidently being construed into meanings which it does not rightly possess. Mr. *Stackemann*, it will be remembered, was in the habit of calling on schools and obtaining permission to take photographs of the premises and groups of the students, in regard to which there was a reasonable certainty of sale (of prints) to the proprietors of the school as well as to the scholars. It was this admission to a certain amount of business which Mr. Justice Farwell went so far as to regard as a "good" consideration—he did not call it a "valuable" consideration—and therefore conferred the ownership of the copyrights upon the school proprietors. It does not therefore follow, in every case in which permission is given to a photographer to obtain certain photographs, that the permission amounts to a good consideration. Far from it. The connection between the photographer and the school proprietor in the *Stackemann* case was very nearly the ordinary one of photographer and customer. The school proprietor wanted the photographs, and the photographer wanted to supply them. Assuming that the photographs were suitable, there was no doubt of their sale to the proprietor, and further, there could be no reasonable supposition that the school proprietors expected the photographs to be used in other quarters. In a case such as our correspondent brings before us the photography is done without a reasonable certainty of its being profitable, and if any profit does accrue, it does not come from the person granting the permission, the relation of whom to the photographer is not at all on a par with that of the school proprietor to Mr. *Stackemann*. It should be clear, we think, that the *Stackemann* decision cannot be applied without a very precise consideration of the facts of a disputed case, and yet—and yet—such is the uncertainty of the law, our advice to photographers whose dealings involve them in such relations, is to come to an understanding in black and white as to the retention of the copyright by themselves. A letter of twenty words, if a dispute comes into court, is worth a hundred rulings of learned judges as to what is and is not "good" or "valuable" consideration.

#### The Hire of Apparatus.

The recommendations which have occasionally been put forward in the German press that the photographic dealer should turn an honest penny by the hire of the more expensive pieces of apparatus used by the amateur photographer come in for a thorough-going discouragement at the hands of a correspondent of "Die Photographische Industrie."

The writer records his disappointment at the returns from the temporary transference of expensive enlarging lanterns and 12 by 10 cameras to his amateur customers, from whose operations the charges for depreciation soon reached a figure which left the dealer nothing for the labour of delivering and collecting the instruments. The only apparatus in which a profitable hiring business could be carried on was, in the writer's experience, a portable flashlight installation, for the use of which for a single evening there was always a brisk demand, and for which the enthusiastic "liebhaber" gladly paid his one mark fifty or two marks when he returned it in the morning on his way to business.

\* \* \*

#### A Suggested Circle Trimmer.

Probably everyone has experienced the liability of the circle and oval trimming shapes to slip while the trimmer is being run round them, especially in the use of glossy prints. This tendency may be easily overcome by the following simple device, which a correspondent sends us:—Around the aperture about three-sixteenth of an inch from the edge bore a few holes with a small fretwork drill and leave the "burr" on. These slight but sharp projections will dig into the waste portion of the print and prevent the shape slipping. The need for a clamp is thus entirely overcome. The process may be carried out with a fine-pointed punch, but this is likely to buckle thin shapes. Manufacturers might take the hint and produce a novelty which would be of practical value to every professional house, viz., a "non-slipping" trimming shape.

#### UNDER WHICH KING, BEZONTIAN?

WE suppose that at the present time there is no more common topic of conversation in professional photographic circles than the entrance of cheap competition into the businesses which cater for the lower middle classes. In various directions the photographer, who has found his customers among the smaller tradesman classes, among well-to-do mechanics, clerks, and other families in the community with incomes ranging from a hundred to three or four hundred a year, sees his business attacked in many directions. First there has been the natural and legitimate competition of his rivals in the shape of lowering prices all round, or of offering a single form of portrait at a very cut price as a bait for further custom. Competition of this kind, which is to be expected in every description of trade, has never been resented by the professional photographer, or feared as a danger for which there was no effective remedy. But of late years the studios catering for the lower-priced photograph have been exposed to attacks from those outside their own ranks in a species of competition for which they could provide no equivalent in the way of counterblast. The last few years have seen the regular portrait business encroached upon by the travelling "sticky back" firms, or other purveyors of cheap bromide prints; they have witnessed the diversion of part of the business to a type of photographer who calls himself an "amateur professional," and of whose methods of doing business the following extract from a letter which we have recently received will give a graphic account:—

I have a little difficulty to contend with, for which I wish to ask your advice. In the first place I am an amateur-professional photographer, first commencing with taking a few photographs, till I have got a little more than I can comfortably manage with devoting the whole of my time to it, and unfortunately I have to take the majority of my clients on Sundays, and on an average I have to take fifty or sixty between the hours of 11.30 and 3.30, and I have only a few slides (six in all) to work with; therefore it means constant changing of plates. I only use half-plates (for I have no use for any other),

from which I get cabinets, panels, ovals, circles, and postcards. I may say that I have no knowledge whatever of the methods of professionals used to a quick trade.

Lastly there have been the cheap copyists and the canvassing firms, whose illegitimate business has been based on profiting by the work of other photographers, or has been fraudulent from first to last, and therefore doubly injurious to the photographic profession by casting the stigma of misrepresentation over all its members. Yet the exposures which the Press in various parts of the country have made of this business has, we hope and believe, checked the evil for a time, if not permanently.

The main fact, however, stands out, that from a variety of causes the price which the cheaper class of photographer gets for his work has gone down, while the cost of production has increased, and as a result of the competition to which we have alluded it is necessary for him to offer a much cheaper article still if he wishes to retain the custom of his poorer patrons.

Turning now to the other side of the shield, the prospect is much more encouraging. In the case of the high-class businesses in the country, by which we mean the one or two in towns of fair size which sustain their reputation for turning out good work and charging a good price for it, the prospect has none of the elements of depression which are suggested by a diagnosis of the smaller and cheaper business. There is proof that the public is willing to come to a studio which can give them good photography and good portraiture, and that it is willing to pay a good price for work which is to its taste, and there is also evidence of the growing disposition on the part of the patrons of such high-class photographic businesses to pay a still more enhanced price for work of a specially individual type.

We are perfectly convinced that the possibilities of offering to a high-class circle of customers portraiture of a type which is a step in advance of the present professional standard constitutes an unexplored field in which should be found money enough to sustain businesses run largely on these lines. However, our present object is simply to emphasise the existence of a market for the better class of work, in doing which we would caution the professional man against the fallacy that he has only to commence turn-

ing out such work to be able to advance prices accordingly. He must not forget that there is the additional task before him of impressing upon the mind of the public the value of his newly-displayed powers.

To glance back over this review of the present position of widely differing classes of business, the present tendency, as we discern it, is for the cheaper to become cheaper, and for the "high-class" to become more "high-class" still. It seems to us that in many instances a photographer will be called upon to decide whether he shall make a bold bid for the cheaper order of patronage, or whether he shall elevate the productions of his studio to a level which, while it assuredly will dissociate him from his cheaper clients, will permit him to do less, and possibly make as much. It is possible that a process of introspection applied by a photographer to his own affairs will indicate to him that in one or other of these directions his business position is susceptible of improvement. Whichever direction he adopts as that in which the movement is to be made it will be inevitable that a portion of his patronage leaves him for his rivals. The gain which he can expect from such a step as we have been considering is in the more perfect adjustment of his business machinery to the production of a commercial article, which is only another way of saying that the step is towards specialisation. We should be sorry to see any greater movement towards the cheaper class of business than has been made of late, yet we are not in the pessimistic mood of those who would see in the multiplication of such establishments a universal degradation of photography in the eyes of the more cultured classes in the community. The distribution of businesses, like other changes in the social cosmos, follow the laws of supply and demand, and unless we are mistaken the growth in numbers of the places where a person who sees fit to do so may get a dozen photographs of himself for sixpence is not a greater departure from established notions of a legitimate price and a standard type of article than has been experienced in other businesses. *En masse* the sources of supply of photographs to the public will adjust themselves, but the fact is no safeguard to any individual photographer that in the process of adjustment he will not suffer extinction. All the more are his energies needed to adapt himself to the changing conditions.

## WORKING - UP AND COLOURING WITH THE AEROGRAPH.

The second of a series of articles on the finishing of prints or enlargements in monochrome and colour by the air-brush. The first article dealt with the general principles of "aerograph" work and the acquirement of strokes, etc. Succeeding ones will treat of the special treatment of the various subjects which professional artists are called upon to work up in black and white and colours.

AND now a little regarding the care of the instrument. That the "aerograph" is a delicate tool can hardly be denied—probably if it were not so it would not do the nicely-conditioned work which the artist requires of it. While the artist who works with brushes may not trouble himself much about keeping his colours scrupulously clean, the worker with the "aerograph" must use constant care not to get dirt or any coarse substance into the colours, and so introduce it into the instrument, as it is liable to choke up the small passage through which the colour comes.

### Cleaning the Instrument.

The accumulation of lint and colour may be prevented by blow-

ing a quantity of water through the instrument each day after using it; the point of the instrument may be dipped in a cup of water, filling the colour receptacle, and then with a high air pressure blown out, working the lever backwards and forwards; the finger may also be placed on the point of the instrument and the air turned in through the water, in this way breaking up any tendency to an accumulation of dirt in the point. Plenty of clean water is a cure for most of the ills to which the instrument is subject. It is also desirable at times to clean the colour from the cap, which may be removed and cleaned inside (with a pointed match or splint), and around the guard with the point of a wet brush.

If more serious disorders exist it is generally best to send it

to the makers, as sometimes more harm than good results from trying to put it right in unskilled hands.

### Colours for Aerograph Work.

Colour should be kept in a closed box or in closed bottles. It is not necessary in working with the "aerograph" to prepare the colours on a palette, as it is possible to modify the tints by adding to them in the colour receptacle of the instrument, and both time and colour are saved. With the "aerograph" great care is not necessary as to the exact thickness or depth of colour to be used, as is necessary with brushes; with a colour of full strength the most delicate tints can be made with the "aerograph," so delicate, indeed, that they may be quite invisible and only become visible by repeating the wash of colour. In this respect the "aerograph" possesses a delicacy which can in no wise be equalled by a stick with a bunch of hair on the end of it.

Moist colours are preferable to dry, as undissolved pieces of colour do not get put into the instrument. If moist colours (in pans) are used they may be taken direct from the pan and put into the "aerograph," adding more or less water as required. For this purpose a No. 4 round hog's-hair brush is the best, and this brush will be found serviceable in washing out the colour receptacle of the "aerograph." When changes of colour are required, have two glasses of water at hand, one in which to clean your brush, and the other with cleaner water to use in preparing colour.

Keep your air pressure high, especially when doing small work; the higher the pressure the finer the grain.

### The Use of the Eraser.

The use of the eraser is very important in "aerograph" work—the colour is not absorbed so deeply in the paper as when applied by a brush, and is to that extent more amenable to treatment with the eraser; the extreme high-lights must be either put on in opaque colour or must be erased; they cannot be left in the working, as they would not have the proper character. The writer is of the opinion that they should be erased. For this you want an ink eraser of the right consistency; a lead pencil eraser will not remove the colour, nor can one use an eraser which is too hard. The writer uses a Hardmuth's typewriter eraser: it is about  $2\frac{1}{2}$  inches long and  $\frac{1}{2}$  inch wide by  $\frac{1}{4}$  inch thick; it is slightly wedge shape, but must be cut with a longer wedge-shape taper on it to give it more flexibility, and the end rubbed to a sharp wedge-point on glass-paper. With this you can soften a shadow, using it broad side on, or can clean up a line or the edge of a tint by rubbing in line with the sharpened edge. It is very important that you have a proper eraser and know how to use it.

In working with a brush you must take infinite pains to soften the hard effects of line and wash. In "aerograph" work you must be put to a little trouble to secure sharpness and definition, and the eraser plays an important part. You need no other implements for erasing except a sharp scraper. The writer has a small flat file ground to a two-edged point. You can buy scrapers, but the difficulty is to get one which will hold an edge, and if the edge is not very keen you make the surface of the paper ragged. There is an art in using a scraper; it should be held with the shaft between the second and third finger and the point between the thumb and first finger, and the hand moved from the wrist in a way to shave the paper, not to dig it up.

Having considered the tools, perhaps the next in order is the question of the enlargement; the question of colours must remain over to a later chapter.

### The Kind of Print for Aerograph Working-up

If the enlargement or photograph were to be finished with a brush throughout, you would ask your printer for a picture with as perfect gradations of shadow as possible; but if the enlargement is to be finished with the "aerograph," you require a chalky print—that is, one in which the more delicate tints of the high-lights are merged in white, the shadows being strong and clean. The reason of this is that with the "aerograph" you can in a very few moments put in all the delicate modelling of the lighter parts of the picture, whereas if the picture is low-toned the small markings caused by the retouching pencil and the defects of the negative will have to be worked out slowly and painfully by stippling, or erasing, or both; your result will not be as smooth or satisfactory when finished as the delicate modelling which you can do in a few moments over the lighter parts of the picture with the "aerograph."

This difference is inherent in the character of the tools, and should not be ignored by the worker; only by taking advantage of such points will success with the "aerograph" method result. A slightly chalky print can be finished as well in one hour as a dark one can be in a day's work.

If the print is being made for colouring, the lights must still be chalky, but the shadow portions must not be made quite so dark or strong as for black and white work.

The texture of the paper on which the photograph is made is important only as affecting the finished result. The "aerograph" will work on either matt or glossy surface, but the non-absorbent surface must be worked slower to permit the colours to dry. We will only say that in our opinion a matt surface is much more artistic than a smooth one, and a moderately coarse grain than a fine-grained matt. The size and character of the picture should determine to a large extent the character of the grain. Prints should be well washed. The writer has seen enlargements turn yellow in parts where the eraser had disturbed the surface, showing that the chemicals had only been washed from the surface of the paper.

### The Best Colour for Black and White.

For finishing black and white portrait enlargements in bromide, the most satisfactory colour is moist water-colour lamp-black, as it is as near as possible the colour of bromide both in the light tint and at full strength. Indian ink is troublesome to prepare, and cannot be obtained in a black the colour of bromide, and must be tinted to match. The lamp-black has also an advantage in erasing more easily—it is absolutely permanent. The quality of this colour varies somewhat with different makers; the writer uses that prepared by Messrs. George Rowney and Co.

For sepia-toned bromides and brown carbons sepia is the most satisfactory colour; it may be obtained in two tints—warm and ordinary—and other colour may be added to match any colour of print. Sepia is a beautiful colour, strong in shadow and clear in its thin tints, works well, and is permanent; it may be best to qualify by saying "practically" permanent.

In the next article we propose dealing with the finishing in monochrome of portraits of various kinds, backgrounds, vignettes, etc.

"CRITERION" Competition.—The following are the prize winners in the Birmingham Photographic Company's recent competition for prints on "Celerio" gaslight and "Criterion" bromide papers, which was open to amateurs only:—First prize (2 guineas), Mr. T. J. Holt, of Manchester; second prize (1 guinea), Mr. H. E. Hall, of Wigan, third prize (10s. 6d.), Master W. T. H. Sampson (aged eleven years), of Tonbridge. The general character of the prints,

however, was of such high excellence that the Company have awarded twelve consolation prizes to the following competitors:—Misses W. and S. K. Jackson, Hyde Park; Miss Keasley, Eastbourne; Messrs. G. H. Thomas, Cornwall; E. C. Ker, Sidcup; A. E. Manning, Birmingham; Adshead, London; J. E. Bradley, Epsom; O. R. Dodd, London; Mr. Freeby, Liverpool; Mr. Budd, Watford; Mr. Dennison, Kendal; and Mr. Parslow, Thetford.

## A PIONEER OF PHOTOGRAPHIC OPTICS.

NEXT Sunday we can celebrate the 80th birthday of Mr. R. H. Bow, C.E., of Edinburgh, who is one of the oldest scientific opticians and photographers living.

There are probably not many readers of this journal who can associate with his name a definite idea of his achievements in this world. His principal work was certainly done in engineering, but he has contributed also enough to our art-science for us to be grateful to him. It may be well to give an outline of the principal points of his work, in which task I hope my readers will make a benevolent allowance for my shortcomings as an exponent of my friend's work.

I think we may speak of his articles and papers under two headings, discussing (1) papers principally of scientific interest, and (2) papers principally of educational value.

Turning to the first of these divisions, our friend's name will always remain associated with correct ideas of distortion. It was he, in conjunction with Thomas Sutton, who pointed out the great importance of the aberrations with which the image of the central spot of a symmetrical objective is rendered by its components, and that in consequence of their presence, a symmetrical objective is really orthoscopic for one scale of reduction only. I have called this Bow-Sutton's law.

I must further mention here his work on equalisation of illumination over a great angle of view. As in collective lenses the thickness of substance steadily decreases towards the margin, he conceived the idea to compensate for the loss from obliquity of incidence by tinging the substance of the crown glass. By those means he took away the greater part of the light in the axial direction, and gradually less towards the margin, thus more equally distributing the remainder over the whole plate. He further advanced our knowledge of this difficult subject by accurate and difficult calculations, which he undertook to illustrate the idea of Geo. H. Slight. In this case the equalisation was very perfectly effected by means of a suitably formed brass plate, mounted a little in front of the diaphragm. As far as my knowledge goes, his two papers furnish to the calculating optician not only a very valuable, but the only source of information as regards the difficult branch of equalisation.

His calculations and experiments on astigmatism are also of great value, however little they may be known at the present day. I may mention here, especially his splendid calculation of the curves of the primary and secondary foci for a thin plano-convex lens in close proximity with the stop. He was able to give these curves for finite angles, and so partially antedated the important result found independently, and verified 37 years later by B. Wanach, of Potsdam, for thin lenses

of any form. We must also remember that he then (1863) published the first plan of correctly registering the results of astigmatic calculations. It was only due to want of space that I dismissed this oldest plan of registration, when I published in 1899, the 48 astigmatic curves in my book, "Theorie und Geschichte des photographischen Objekts."

Concluding now under this heading, we must affirm that we see in his work the features of a scientist well versed in mathematical methods, and of a photographer who had love for our art-science, an eye for its wants, and the patience to supply them.

His achievements in the educational line are not less, although they also are entirely forgotten. Personally, I am inclined to see his principal merit in his endeavour to emphasize the fact of an orthoscopic photograph's being essentially a correct perspective. In consequence thereof he represented the photograph often, not at the place of the ground glass, but between the objects and the lens. He even went so far as to devise a special instrument, with the object of viewing transparencies made with short focus lenses as from the correct standpoint, i.e. under the same angle which the object themselves presented to the photographic lens. The way in which the lesson taught by him was received by the public, was in a certain manner prophetic; all his endeavour could not induce his fellow-workers—even at that time of high standing—to see with his eyes and to understand his well-developed and important ideas, and the absolute want of interest seems to have had the effect of slackening his zeal as a teacher.

He took a great deal of trouble in his earnest endeavour to re-

suscitate stereoscopic photography in the beginning of the sixties of the last century. We know now that this task was hopeless for anybody, however gifted; it was simply impossible then to stem the tide of an universal disgust, swelled by an injudicious overfeeding of the curiosity of an imitating public. But the manner in which he tried his hopeless task is worthy of record. He approached his subject scientifically, and tried in two masterly papers to give a theory of this instrument, based on the supposition that the degree of convergence of the axes of the eyes has little or no effect upon the apparent *absolute* distance of the object observed. Not even at that period, the beginning of the sixties, when scientific men of acknowledged position still took an active interest in the stereoscope, are—as far as my knowledge goes—many papers extant which could be very well compared with his two series. He seems to have stood alone when he pointed out a remarkable error into which Sir David Brewster had fallen: a remarkable error, as three scientists of note, A. Claudet, Sir David Brewster, and H. Helmholtz, had independently altered

ROBERT HENRY BOW, born at Alnwick, January 27, 1827.

their originally correct opinions as to the same (erroneous) conclusion.

When, towards the end of the sixties, the general interest in photographic subjects slackened, R. H. Bow also turned to different topics, but he was easily brought back to photographic questions. An instance is given by the active interest he had in, and the new ideas he worked out for anamorphic photographs, where length and breadth of the original are reproduced on different scales.

His last work, done a little more than a year ago, was on an astronomical subject; he devised a very practical and useful star chart to enable the amateur astronomer to immediately point out the place of a planet with reference to the different well-known groups of fixed stars.

The authorship of the present article shows that in R. H. Bow's case, too, the old saying holds good, no man is a prophet in his own country. It is certainly a pity for both parties, and I for one should heartily wish to give up my place of biographer to a countryman of his. But as it is, these poor words ought to stand as a small token of my gratitude for much kindness I have received during the nine years of our acquaintance. By a

happy chance, it is nine years to a day on his birthday that—having discovered his address—I wrote to him and sent him an historical article of mine on distortion, the principal contents of which were an exposition of Bow-Sutton's law. As his paper had been written in 1861, I had, in composing my article, not the slightest doubt that the author had long since been called to his fathers. From that time we have kept up a steady correspondence, principally on optical subjects, and it has been my good fortune to enjoy his hospitality, to see him in his hale and hearty old age, to discuss different topics of scientific, political, and literary interest. If anything was wanting to crown our connection, it was Mr. Bow's personal acquaintance with the late lamented Ernst Abbe, with whom I have sometimes discussed my friend's merits. But Mr. Bow's great age was naturally an obstacle to a meeting between the two.

I have nothing more. We will all wish that many years more may be his lot, with the strength of mind and body to enjoy them, and will do our utmost to impress his name and a knowledge of his work on our friends and pupils.

MORITZ VON ROHR.

## ADVERTISEMENT PHOTOGRAPHS AND CHILD MODELS.

THE photographs reproduced in our issue of January 4, by courtesy of the S. S. McClure Company have brought us an extract from a recent issue of the *American Printer*, in which is an account of the photographer, Mr. A. B. Phelan, to whom was entrusted the task of producing them in response to the request of McClures to provide a graphic representation of *McClure's Magazine* as "The Market-place of the World." The photographs, as our readers will not need to be told, are made up by pasting together prints of a large number of detached scenes. Mr. Phelan claims no originality as to "composite" photography, except that he has harnessed the idea and directed intelligently towards useful ends. It may be interesting to quote what the *American Printer* and the McClure advertising management think of the photographs. Our contemporary, which may be regarded as an authority in illustrative advertising, says:—

"Doubtless this is but the initiation of a new art feature in the illustrative world, at least in the advertising field, and the writer looks confidently forward to many elaborate and skilfully executed designs of this peculiar kind in the early future, from the office of McClure's, where this idea has been so fully developed.

"The advertising manager of McClure's himself is enthusiastic on the subject, and holds a decidedly favourable opinion as to the power of the composite, elaborated as it is and is to be, in firmly fixing in the mind of the public the fact that *McClure's Magazine* is 'The Market-place of the World.' This statement is not used merely as a catch phrase, but thoughtfully, and after due consideration. He says: 'That Mr. Phelan has been able to visualise an ideal by that most realistic of all arts—photography—so that the picture conveys the unreal by photographing the real, and at the same time conveys an actual truth, is his great "feat."'

"The advertising pages of *McClure's* treated as a great market-place is a fantasy, and yet in its broadest sense it is "The Market-place of the World." Now Mr. Phelan has visualised the fantasy so as to convey the reality more strongly and in such a way as to fix it more firmly in the minds of our readers than could possibly be done in words. This is his 'feat.'"

The professional advertisement photograph is more often

seen in the American magazines than in those in this country, and it may be of interest if we reproduce two, which we find

A Photographic Advertisement of Jaenicke's Inks.

in the current issue of a leading printing journal, the *American Printer*. The "Street Scene" is one of a series of advertise

ments of Jaenicke's inks, each representing an incident in the travels of the big man in search of information about Jaenicke's inks. The first of the series had shown him en route to New York by railway, but no railroad car serving to accommodate him, he is stretched full length on the top of the train.

The other advertisement (of the necktie) is a selected example of similar work, though the reproduction on this page, which is from a half-tone, falls a good deal short of the original.

'A Striking Necktie Advertisement

In reference to the same subject of photographic advertising, Mr. Hamilton Smith, of Devizes, sends us an example of a photographic cover design made by him for the *Caxton Magazine*, to which was awarded a gold medal in a competition for designs recently held by our contemporary. The design, which, by Mr. Hamilton Smith's kind permission, we reproduce herewith, has no special reference to the printing craft, and in this respect

An Advertisement Photograph by Hamilton Smith. Awarded First Prize in the Caxton Magazine Competition.

is all the better from the photographer's point of view, inasmuch as the same subject can be offered to different firms in various distinct trades. Mr. Hamilton Smith sends us a circular showing his design being very effectively used to advertise boys' clothing. Mr. Hamilton Smith also allows us to reproduce a photograph, by himself, which may have caught the eye of some of our readers, as a showcard of the Kodak Co., by whom

it has been used for this purpose. The photograph is a good example of the effective use which can be made of very simple accessories and models, and is an answer to the objection which is made to advertisement photography, that the cost of models

Advertisement Photograph by Hamilton Smith.

runs away with the profits. Still, the objection does apply in many cases, and the professional advertisement photographer finds it pay to secure the services of practised models, among which, children, as well as adults, are to be found. In this connection the experience of a New York photographer, published in *Wilson's Magazine*, may interest those whose intentions are in the direction of this special branch of photography: "Beauty is, of course, the primal requisite. While the infantile type is preferred by many, the piquant child has many admirers.

"Girls, particularly blue-eyed tots with curly golden hair, snub noses, dimples and round chubby faces, are eagerly sought, as they make pretty angel heads and are particularly adapted for ideal pictures for art and commercial purposes. They must be plump.

"Little girls with straight locks haven't the same chance of getting employment as those with ringlets. To some children posing is as natural as breathing. They fall into graceful postures very easily. Others are naturally awkward, despite their pretty faces and winning ways.

"As to the remuneration which these little artists receive, it varies to no great extent from that received by their older sisters in the business. An hour's posing generally brings from \$1.50 to \$3, and after an hour's work the average child is generally too tired to sit longer.

"It is understood that the children shall furnish their own costumes, unless it is a character costume, in which case, perhaps, the professional costumer will be called in. Most of these children have good wardrobes of simple, dainty gowns, used expressly for professional engagements. But the other day a dirty, but undeniably pretty Italian child, was brought in here by someone who picked her up in the street.

"A very soiled and ragged cotton dress barely covered the little one's nakedness, but there was a charm about the kid that was simply irresistible, and so I took her just as she was. The picture will be used for a dyeing and cleaning establishment, and it will be a winner, if I mistake not. But that is the exception that proves the rule, of course.

"I am besieged with applications from mothers who wish me to use their children as models, and while some of the children, nearly all of them I might say, are pretty in their own childish fashion, few of them are sufficiently artistic or picturesque to be made use of. If a child possesses those qualities, and in addition can take poses naturally and prettily, there isn't a doubt that she can find plenty of work.

"If a mother has a child of whom she wants to make a model and the little one is of a nervous temperament, I should first advise that the child be put through a course of gymnastics or

physical culture until she gets hold of herself, and is able to control her muscles and nerves. Exercise of this sort is an aid to grace, and makes posing less tiresome.

"Most children love to pose, and I have frequently seen children cry when it was time for them to leave. Others sometimes have tantrums when asked to sit before the camera, and it is only after all sorts of promises of candy, toys, and the like, that they will consent to pose.

"Child models reach the awkward age the same as other children, and one of the most pathetic sights I have ever witnessed was when one of these children, after having posed successfully for half a dozen years, finally reached the hobbledehoy stage, when to assume a graceful attitude was manifestly impossible, and poses that once were simple and pretty were difficult to assume and ugly to reproduce, because of the consciousness of the child."

## RENAISSANCE OF PORTRAITURE BY PHOTOGRAPHY.

[The following article by Mr. J. C. Strauss of St. Louis, a collection of whose photographs is now being exhibited, with those by other American professionals, in the "little gallery" at the BRITISH JOURNAL Offices, will doubtless be read with interest by all who have followed the career of the talented writer, or are taking the opportunity which is now offered of seeing some examples of his current work. The article is from a recent issue of "Wilson's."]

SINCE the earliest times the visible object of greatest interest to humanity has been the human face and form. Attempts at picturing man were among the first efforts towards reproducing the images most deeply impressed upon the mind. These crude representations not only excited interest, but by degrees became the object of admiration and veneration. Man often could find nothing worthier of his worship than images of himself. This worship developed to such an extent that one of the first and most important laws, at the very base of our present civilisation, forbade idolatry—the ascribing superhuman and supernatural powers by man to images or pictures of himself. The Greeks had no brighter laurels or higher honours than for the sculptor and painter, who most beautifully portrayed, in canvas or in marble, the features and form of man and woman.

This condition could not have existed had not the great masses been peculiarly and deeply interested in and attracted by reproductions of the human face and body. While the masses, from the dawn of history onward, have always admired pictures of people, and taken advantage of opportunities to view them, it was not until the advent of photography that personal possession of portraits came within the possibilities of others than the wealthy and powerful.

### The Obsolete Album.

The family album full of cabinet "photos" was, for a number of years, one of the favourite themes for jests by the paragraphers of the papers. They forgot, or probably never knew that an interest in the pictures of people is almost as historical, as universal and as natural as breathing.

With all the other attractions and diversions of a metropolis, a recent exhibition of photographs at the Chicago Art Institute was visited by over 55,000 persons, "the highest attendance for the same period of time in the history of the institution," says a Chicago periodical.

Aside from electricity, no other development of the last six decades has become such an important factor in the daily life of the masses, as is applied in so many and to such widely diversified uses, as photography. It enters by numerous channels of greater or less importance into almost every phase or aspect of human endeavour. It is essentially an element to be considered whether one's activities are in any of the paths of art or of science, of mechanics or of commerce, of literature or of recreation.

Photography has become practically an omnipresent element in our civilisation.

As applied to portraiture: Photography may now be said to be in its renaissance. Its earliest development, that of the daguerreotype, had a distinctive art element because of the individuality of the pictures. There were no duplications. The then known processes required a degree of skill on the part of the maker and

a length of time to secure results which of necessity made the portrait one free from faults of the mechanical prints which followed as the processes were made simpler. As, year after year, the manipulation of plates and papers became more easy, the photograph departed from the higher qualities of the daguerreotype and the evidences of machinery and the tendency towards commercialism increased. The descent was rapid and deep. The first downward step was taken when quantity became the important factor, and instead of individual pictures, repetition and duplication set in.

### The Baneful "Dozen Price."

He who first proposed that photographs should be sold by the dozen, just as eggs or socks, pointed out the path which led to the discrediting of camera portraiture, inviting the scorn of the artist.

Canvases painted over with impossible landscapes for backgrounds, and papier maché moulded into ungainly accessories, followed. Certain stilted, conscious posings of subjects became the rule, and naturally pictures made by any one photographer were such a close resemblance to the work of all others that it made but little difference which "artist" was patronised, the finished product was just about what would have been obtained had some other "studio" been visited.

Pictures by some of the best-known photographers, even those of New York City, could be recognised by the scenery and furniture because of the constant recurrence of the same pieces in their work. The standard conception of art was a face modelled like a cheap china doll. Each was smooth, puffed, and rounded without a line of character, and the skin as white as a new paper collar.

### A Revolution in Methods.

One of the first changes of infinite relief to sitters was the abolition of that instrument of torture, misnamed a "head rest," but in truth a vice which chilled the marrow of the subject. Next the papier maché settees, balustrades, and fences were converted into kindling wood. The snow-capped mountains, the unending meadows, and the tremendous waterfall were thrown into the ash heap. The little card stuck on a pole, towards which the victim must look pleasantly, was "fired." The constrained, affected poses were abandoned. The relative difference in various shades of colour were considered. The over-retouching which left faces blank, putty-like lumps was rejected. The stupid method of making pictures of different persons, or of the same person in different poses, accommodated themselves to a predetermined size or shape of mount, was abandoned. This revolution of method, this endeavour to educate out the wrong conception and to teach correct principles has taken years to reach its present status, where connoisseurs and critics admit the art element and value in camera portraiture. Necessarily much

misconception remains, and the enlightening movement advances but slowly.

The repetition of backgrounds, the conventional, theatrical poses, the harsh contrast of black and white, the removal of lines of character, the uniformity of size, governed by mounts—these are some of the well-known features of the photograph which are still too prevalent.

#### The Study of Subtle Tones.

The photographer who really has an earnest desire to make his work something more than a mechanical impression or map of the subject, gives to each print leaving his hands the stamp of individuality. The materials selected are such as will lend themselves to the desired colour tones and yet possess absolute permanence. Each impression receives individual chemical treatment—this in sharp contrast with the ordinary photograph of which hundreds may be treated in a mass. The background in each plate is essentially different from that on any other, being sketched by hands skilled in artistry—thus the background harmonises with the subject and is in accord with the lights and shades of the portrait,

making a pleasing general effect or ensemble. The size and shape of the portrait is also a matter of considerable study, no two poses being treated identically. The form and dimension are made to adjust themselves harmoniously to the picture—so also with the colour; instead of harsh contrast of light and shade there is a gentle gradation with truthful regard to their relation in life. Where the white lace falls upon the wrist of a lady there is a difference of many shades between the flesh tone and that of the lace. In the photograph it would be false to make both appear alike, or nearly so.

And so on in each and every distinct detail of true portraiture by photography, the one trait ever present is individuality. Just as no two persons or faces are identical, the portraits should vary.

To secure this individuality of treatment requires trained assistants, having an artistic temperament, in all the departments of a photographic establishment. Such a portrait as is here contemplated evidencing the artist touch throughout can be obtained at a cost but little greater than that of the stereotype description. But when it is received it measures up to the highest standard—"a thing of beauty, a joy forever."

J. C. STRAUSS.

## PHOTOGRAPHY FOR HISTORICAL PURPOSES.

[In continuation of the article which appeared last week on the emanated from Brussels, we publish a paper from our Berlin contemporary, "Die Photographische Industrie," which deals, as we think, with a more possible solution of the problem of placing at public and private

suggested scheme of photo-micrographic reproduction, which has been suggested by the German photographic industry, which deals, as we think, with a more possible solution of the problem of placing at public and private collections.—EDS.]

A PHILOLOGIST has just written a book on the value of photography to science; that it is a good book will be at once obvious from the author's name, Dr. Karl Krumbacher, Professor at the University of Munich. The lessons, which are the results of the author's many years' experience, appears to us to be so important for the manufacturer and dealer, that we must consider them more closely.

The problem set is a triple one: the manuscript and book treasures ranging from a period of over two thousand years, and scattered throughout innumerable libraries, are constantly exposed to the danger of destruction. Turin and San Francisco are two examples. Transcripts of the most important of all writings are, in the case of destruction of the original, of but little value;—photography only can supply the substitute; the most important works must, therefore, be reproduced as faithfully to the original as possible and the originals kept in other places. Comprehensive philological and historical work are only possible after the collection and sifting of innumerable materials. Countless transcripts of works, which are distributed all over the world, must be made for this. The work will thus extend over years and decades, if the searcher wishes himself to take all available transcripts. Old philological information, the introduction of historical research, is only to be advantageously gained first hand from the old works themselves, or from faithful reproductions. A draughtsman's copy can never be absolutely satisfactory.

In all these cases photography, and only photography, can be of actual assistance; and then only if it can be cheaply worked, for it means in all cases a very large number of exposures. The professional photographer can never satisfy this requirement; to entrust priceless originals to him is not advisable—Krumbacher reports some hair-raising cases. If he is to make the exposures away from his studio, he must charge so much that his help would be worthless. The investigator is, therefore, forced to do his own work, and requires, to be able to do it, the support of the manufacturer and dealer.

An enumeration of the requirements of the investigator will make this clear.

Generally a copy is required of a great number of pages; it is therefore desirable, on account of quickness and cheapness, to work so that the negative can be used as the final image; that it is reversed as regards light and shade is of no moment, for one can frequently read the letters more easily if it is so; only the negative must be on paper, and ought not to be laterally reversed. The arrangement which was suggested by Grafflin in 1900 would answer these requirements; the book or manuscript to be reproduced is laid flat on a stool or low table, and, if necessary, a sheet of glass

laid thereon to keep it flat, and now photographed with an ordinary bellows camera with a reversing prism in front of the lens. For the negative a kind of film magazine<sup>1</sup> provided with rolls of bromide paper should be used; with this arrangement from one hundred to three hundred negatives can be made in a day.

Up to the present, however, manufacturers have not entered upon this branch. The existing arrangements are defective and too dear, and quite a simple bellows camera is wanted, which when set up on a firm stand will not alter its position when a full dark slide is inserted. A magazine roller slide, which can take sufficient paper for twenty 7 x 5 or 9 x 7 exposures or more, an outside and easily read recorder, and a sharp marker to differentiate between the various exposures, should be fitted. Another requirement is that the rolling up should be effected without any great strain on the paper, and that everything should be firmly constructed.

No particularly great stress need be laid upon the lens; this would always be used with small stops, so that a good applanatic lens, preferably an anastigmat, working at  $f/8$ , would suffice.

The most ticklish point is the reversing prism. Must this be actually as dear as it is, considering that it is not to be used for delicate industrial reproduction work, but only for the special work herein outlined? Reversing with mirrors should be taken instead of prisms.<sup>2</sup>

The way in which the negative material is supplied is very unsatisfactory. The paper must be wound on the rollers by the operator himself. It would be necessary for the paper to be supplied already rolled and packed so that it can be used like the daylight loading film cartridges.

The taking of manuscripts on a yellow or brownish ground gives no satisfactory results according to Grafflin's process, as the bromide paper used is not sensitive to yellow. Krumbacher says "the trouble may be overcome either by using orthochromatic plates or yellow screens," and bewails the fact that "an important difference between negatives taken without the yellow screen and with the longer exposures could not be recognised." This is however easily explained, as prolongation of the exposure and the use of yellow screen does not give an orthochromatic rendering on monochrome sensitive films. It would be necessary to prepare yellow

<sup>1</sup> The old roller slide, as was first used for negative paper, and later for cellulose films, would of course be the best thing to use.—EDS. B.J.

<sup>2</sup> An arrangement of this kind is figured on page 729 of the ALMANAC, 1907. It suggests that the reproduction of old MSS., palm-leaf MSS., etc. is not as delicate as ordinary industrial reproduction can hardly be endorsed. Certainly, in some cases such as in old Arabic, Persian, Hebrew, and written characters of like nature, the work is more delicate.—EDS. B.J.

sensitive bromide paper. That this is possible is proved by the publications of Andresen and Ruzicka ("Eder's Handbuck," fifth edition, p. 764, et seq.), who sensitised bromide paper with rhodamine, so that it possessed a maximum of sensitiveness in yellow near the D line.<sup>3</sup> This, again would be a thankworthy matter for the maker.

One possibility Krumbacher did not see, and that was the use of negative paper instead of the ordinary bromide paper. The advantages of this are in the greater sensitiveness of this paper and the possibility of taking contact prints from the negatives if required, as the specially thin paper permits of easy printing, which is not the case with bromide paper.

For specially difficult cases one would naturally use ortho or panchromatic plates with a colour filter and without a reversing prism, and the camera could be arranged with its axis vertical by means of one of the cheap ball-and-socket arrangements.

The exposure of the paper must be so estimated that the development can be pushed to its end, and not be stopped prematurely; absolute pure whites and deep blacks will be obtained rather by too short than too long exposure. Of all developers ferrous oxalate will alone give perfectly satisfactory results in all cases. Thorough fixation to avoid subsequent trouble will obviously be necessary.

Krumbacher has some valuable notes as to the advantages of the various photomechanical processes for the preparation of charts for paleographic works. Photogravure and photolithography are not capable of competing. If the test without the ground is to be reproduced, then the simple zincography is the cheapest and gives extremely clear results. Collotype reproduces all the details of the original; but, assuming that a thousand pulls (10½ x 7 inches) are required, it is about four times as dear. The half-tone and the new Spitzertype processes are about the same in price—that is, about double that of zincos; they are neither free from faults, however; the half-tone screen destroys the finest details. Spitzertypes give brilliant and sharp pictures, which are, however, false in the middle tones, so that they are hard and scratchy. In every case, to select the process which shall be satisfactory requires much consideration.

Rapid machine printing of bromides does not appear to have been taken into account by Krumbacher; if this cannot compete with the three cheaper processes, it certainly can with the dearer collotype, which it surpasses as regards clearness and richness in the finest details.

Is any clearer enunciation required of what is wanted for photo-historical work? There is no apparatus, no negative material, and no slides for this work. There exist only the innumerable manuscripts, which should be cheaply reproduced, and the experts who sadly need such reproductions, and who, by their absence, must lavish enormous amounts of time and money.

To make—and make cheaply—such apparatus and material should be the task of the manufacturer.

To introduce these with corresponding urgency everywhere that the need of them may be expected, to the superintendents or administrators of every library and museum, should be the remunerative task of the dealer. For this class of work he could hire out the necessary apparatus, and develop the rolls of paper. Above all things he may be sure that where there is continued need of such work, and the apparatus has been proved to be efficient, it will be bought; for it belongs undoubtedly to the collection of every teaching chair of paleography, diplomacy, archaeology, and history, as well as every public library.

The Manchester Amateur Photographic Society has just issued its annual report, which discloses a very satisfactory state of affairs. The membership has increased, there is a substantial balance in hand at the bank, and the year's work in general indicates a high standard of efficiency and continued progress.

<sup>3</sup> The author is completely at fault here. Andresen's suggestion, which was made at the Congress for Applied Chemistry, held in Vienna in 1893, was for preparing a colour-sensitive and print-out bromide paper for the photometric or actinetric purposes, and had nothing whatever to do with developed bromide paper. Andresen's suggestion was to bathe raw paper in potassium bromide solution, dry, float on silver nitrate solution, wash, and immerse in sodium nitrate solution to which some rhodamine B was added. Ruzicka ("Wiener Kilnische Wochenschrift," 1902, p. 637) used Andresen's paper, but coated it with auramine dissolved in collodion, and thus estimated the visual luminosity of the light. For negative work, precisely the same methods, either by bathing or adding the dye to the emulsion, must be followed, as in the manufacture of films or plates.—FHS.B.J.

## Photo-Mechanical Notes.

### How to Correct Screen Distance Scales.

MM. H. CALMELS and L. P. Clerc described in a recent communication to the Société Française the following method for checking the graduated scales engraved on process cameras. A stop is cut (as shown in Fig. 1) with two small holes which are on a diameter parallel to one of the lines of the screen and at equal distances from the lens axis. The distance from centre to centre of these holes should

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

Fig. 6.

Fig. 7.

Fig. 8.

be about one-sixteenth of the focus of the lens. The screen should be placed at the maximum distance, the camera focussed sharply on some document placed on the copy board, and then a sheet of white paper, illuminated as strongly as possible, should replace the document. The special stop described above should then be inserted, and the screen racked back as far as possible. If there was contact

between the plane of squares and the focal plane, the ground glass would have the appearance of a series of squares (fig. 2). As a matter of fact, in consequence of the separation by the thickness of the glass between the engraved surface and that of the screen supports, the ground glass presents a series of oblong luminous spots (fig. 3).

If the screen is very slowly separated from the ground glass there will be seen two luminous spots (fig. 4) corresponding to the transparent parts of the screen, which become progressively separated one from another (fig. 5) in proportion to the increase in the distance of the screen, till two spots corresponding to two neighbouring clear spaces begin to coincide (fig. 6). We will call this position of the screen the first position of coincidence.

Continuing to increase the distance of the screen, the two spots corresponding to each screen space get farther and farther apart. The coincidence thus ceases until for a given distance a new coincidence is established between the spots corresponding to two screen spaces separated one from the other by a clear screen space: this is the second position of coincidence (fig. 7).

It is easy to calculate that the distance which separates the two positions of coincidence is equal to that which at the time of the first coincidence separated the actual screen plane from the focal plane.

Considering fig. 8, in which the distance of separation of the screen are considerably exaggerated for the sake of clearness, there are represented:—

$d$ , the distance from centre to centre of the two apertures of the diaphragm;

$t$ , the extension of the camera, measured from the diaphragm or its image;

$l$ , the sum of an opaque and transparent space of the screen;

$e$ ,  $e^1$ , the distances between the actual screen plane and the focal plane in the first and second positions of coincidence.

From elementary geometrical considerations based on the similarity of triangles we have for the two positions of coincidence, the ratios.

$$(1) \quad \frac{t}{d} = \frac{e}{l}$$

whence

$$(2) \quad \frac{t}{d} = \frac{e^1}{2l}$$

$$e^1 = 2e$$

Supposing, for example, that the index of the screen gear had marked on the divided scale 2 mm. for the first coincidence, and 7 mm. for the second, the distance between the two positions of coincidence being 5 mm., this number also measures, in the first position, the effective distance between the screen planes, and we know consequently that all the distances read upon the scale ought to be increased by 3 mm. every time that the screen tested is used, and that the same slide should be next the dark slide, the two faces being easily distinguished by the maker's mark engraved on one of them.

#### Resin-Gr in Half Tones.

A process in which a selective grain is distributed over a print metal intended for the production of a photo-engraving has been patented in this country by Messrs. Klimsch and Co., of Frankfurt. The process, as described in the specification, No. 27,158, 1905, consists in applying to the printed, but undeveloped plate, a solution of resin in a volatile solvent, and it is of the highest importance that the temperature of the plate and the humidity of the atmosphere in which the application of the volatilisation take place shall remain perfectly constant. These operations are, therefore, done in a box, which is maintained under standard conditions in these respects.

The box must be made rather large, as otherwise the vapours emanating from the resinous solution during evaporation would have a harmful effect on the formation of the grain. The production of the grain when volatilising the solution on the sensitised plate is dependent upon a series of conditions such as the degree of exposure, the quality and quantity of the resin, the quickness of the evaporation, etc. Variations of these conditions would change the character and arrangement of the dots, so that it is of utmost importance to keep the conditions perfectly constant.

Immediately after the grain is produced the plate may be etched by means of dilute nitric acid or other suitable etch, and the plate then gummed and treated in the usual manner. Instead of etching the

plate directly after the grain has been produced, the chromate salts may first of all be washed out of the coating. To sensitise the plate there may be used besides the chromated albumen other sensitised organic substances such as gelatine, glue, fish-glue, gum, etc.

The coating producing the grain may be composed of other substances besides common resin, such as mastic, elemi, sandarac, amber, gum damar, gum copal, asphaltum, dragon's blood, shellac, fir-resin and sundry balsams; also greases, oils, etc. These substances can be used according to the circumstances, pure or mixed suitable dissolving mediums being used.

Instead of the alcoholic solution of resin there may be used with good results a mixture of petroleum, ether, and alcohol; it is advisable, however, to subject the former to a partial distillation and use always the same proportions. Nearly all the ingredients added to the sensitised coating or to the resinous solution have a certain influence on the formation, even if the substances added can be considered as neutral or of having little effect. It is impossible therefore to enumerate here all the ingredients which may be added and the effect they will have on the sensitised plate. Special attention is drawn, however, to the following points:—Calcium chloride added to the resinous solution produces the eliminated dots in the light parts of round shape and spaced at large distances apart. Turpentine, according to the quantity used, results in a close shading being obtained in the formation of the grain, and a round grain in the light parts.

Alkalies, especially ammonia, cause a better adaptation of the grain to the tints of the copy. An increase of the concentration of the resinous solution gives a coarser grain, which result can also be obtained by varying the speed of the whirler upon which the plate is placed during the evaporation of the resinous solution. It is obvious, therefore, that by varying the concentration of the solution, the ingredients used and the speed of the whirler, the operator is able to obtain any fineness of grain desired. The process is applicable to every method of printing, and is of special advantage in colour printing owing to the fact that the grain is not arranged according to a system of lines and all production of "moiré" being entirely excluded.

## Exhibitions.

### LIZARS' £200 EXHIBITION.

THE exhibition now open in the Royal Institute of Fine Arts, Glasgow will undoubtedly do much to attract attention to photography, and as such will no doubt act for the betterment of photography as a profession and as a hobby.

The eighty-seven prizes offered have drawn forth 800 prints, and these are arranged as well as can be expected, considering their varied quality. There is undoubtedly some very beautiful work, though some of the entries make one wonder if their perpetrators ever saw an exhibition; but even if they had not done so, one would have imagined that the educative influence of the photographic Press, illustrative as much of it is, would have taught them the main necessities of a picture, but evidently there must be some who—terrible thought—read not photographic papers.

The judges—Sir Francis Powell, President of the Royal Society of Painters in Water Colours; Sir John Ure Primrose, Bart., President of the Scottish Photographic Federation; and Mr. C. F. Inston, F.R.P.S. have, in the words of one of the evening papers, made their awards "on the principle that the photographs must be 'straight photographs,' without fake." Then the erudite pressman adds: "A highly satisfactory principle, when it is to be remembered that in the past, first award gold medals have been known to be won by prints taken from the back of a negative." The above critique shows a sadly debased conception—the back of a negative, forsooth!—of the high and lofty aims of the impressionist school.

Mr. W. S. Crockett, hon. president of the Glasgow Eastern, a well-known worker, gains the premier award, £20, with a picture of Sterling Bridge, while hard behind comes Mr. Dan Dunlop, Motherwell, gaining second prize (£8) with one of his birch pictures. 'Twere tedious to endeavour to detail the eighty winners, but one could not but be struck by the fact that many winners of the past had been backseated—pictures that had gained sheaves of awards were "sent empty away."

The only professional to take advantage of the opportunity and draw the attention of the many visitors to his work was Mr. Warneke, who had a strong display which ought to result in an acceleration of business. The business man always takes advantage of these advertising changes.

As is natural, Lizars' Challenge camera in a many forms occupies a prominent place in the show—as it is the cause of the pictures, it is only meet that it should receive an honoured position.

The advertising scheme is a big one, but the firm of Lizars has tried the same before, and no doubt the results on that occasion were satisfactory, or the project would not have been repeated.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between January 7 and 12:—

**COLOUR PRINTS ON WOOD.**—No. 394. Process or means for obtaining single-colour or polychromic direct impressions on wood. Ernest Jozs, 37, Essex Street, Strand, London.

**CHANGING BOXES.**—No. 480. Improvements in photographic change boxes. George Russell Nicholls, 48, Crescent Road, South Norwood Park, London.

**COLOUR SCREENS.**—No. 495. Improved method of producing three-colour screens for colour photography. Robert Krayn, 33, Cannon Street, London.

**FILMS.**—No. 524. Improvements in or relating to apparatus for the development of photographic films. Kodak, Ltd., Chancery Lane Station Chambers, London. (Robert Kroedel, United States.)

**CAMERAS.**—No. 561. Improvements in photographic cameras. Henry Hartley and William Henry Bayliss, 11, Burlington Chambers, New Street, Birmingham.

**CINEMATOGRAPHS.**—No. 623. Improvements in transmission mechanism for apparatus used in taking or reproducing animated and other pictures. Henri-Louis Huet, 53, Chancery Lane, London.

**DISHES.**—No. 638. Developing and washing dish (photographic). Charles Davis, 117, Warwick Street, Leamington Spa.

**FRAMES.**—No. 747. Photographic printing, vignetting, and speed-testing frame. Robert William Wilson, The Stead, Windy Nook, via Gateshead-on-Tyne.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**PRINTING MACHINE.**—No. 26,740, 1905. The invention consists of a cylinder machine for copying tracings. It consists of a glass cylinder open at the ends, inside which are mounted the electric lamps, mercury vapour tubes, or other suitable artificial light. The cylinder is surrounded almost completely by an endless band, such as the travelling blanket arrangement commonly employed in calico printing. The tracings to be reproduced are fed with the sensitised material between the endless band and the cylinder, so that all three travel together round the surface of the cylinder, which they rotate by contact, and the printing sensitised material and tracings are then led from the endless band preferably on to separate batch rollers.

In the figure—*a* designates the glass cylinder which may be of any suitable length and diameter.

The cylinder *a* is mounted upon any suitable number of anti-friction bowls or rollers *b* so as to be free to rotate thereon. The endless band *c* of blanket cloth or other suitable material is driven by a roller *d* fixed on a shaft *e* driven in any convenient manner, as, for example, by a spur wheel *f* and a pinion *g* on a shaft which may be actuated either by hand or power. The endless band *c* passes almost entirely round the surface of the cylinder *a* and is supported on guide rollers *h*, all or any of which may be adjustable so as to regulate and maintain the tension on the endless band *c*.

The tracing *i* to be reproduced is led from a batch roller *j* and the sensitised material *k* from a batch roller *l* and passed round the surface of the transparent cylinder *a* between it and the endless band *c* with the tracing next the cylinder, and are taken finally to two separate batch rollers *m n* upon which they are wound respectively as they leave the cylinder. The pivots of the rollers *m n* are supported upon inclined arms, not shown, one at either end of the rollers, so that the roller *n* on which the tracing *i* is batched lies in frictional contact with and is rotated by the endless travelling band *c* and the roller *m* on which the printed sensitised material is batched lies in frictional

contact with and is rotated by the tracing on the roller *n*. The lamp *p* is placed inside the transparent cylinder *a*. When the endless band *c* is set in motion by the rotation of the roller *d* the tracing *i*, the sensitised material *k*, and the transparent cylinder *a* all move together at the same surface speed, and the material *k* is printed with the impression of the tracing by the action of the rays of the light within the cylinder. After printing the material *k* is wound upon the roller *m* and the tracing *i* upon the roller *n* as they leave the cylinder, while the endless band *c* continues to travel over and under its guide rollers *h*.

Instead of driving the cylinder *a* by frictional contact with the endless band *c* only, it may be geared so as to drive it at the same surface speed as the endless band. William Mycock, Worsley Street Engineering Works, Salford, Manchester.

The following complete specification is open to public inspection before acceptance:—

**COLOUR PHOTOGRAPHY.**—No. 194, 1907. Manufacture of screens for use in colour-photography. Du Hauron and De Bercegol.

## New Trade Names.

**ORTHOCHROME.**—No. 288,475. Plates included in Class 1, prepared for photographic purposes. The Imperial Dry Plate Co., Ltd., Ashford Road, Cricklewood, London, N.W. Manufacturers of photographic materials. December 3, 1906.

**HAZEET.**—No. 288,534. Chemical substances used in photography. Cyril Thurland Thonger, 14, Cape Hill, Birmingham. Manufacturer. December 5, 1906.

**THE ILFORD RAPID ISOCHROM PLATES** (including design of label).—No. 288,397. Photographic dry plates. Ilford Ltd., Britannia Works, Roden Street, Ilford, London, E. Manufacturers of photographic plates, papers, and films. November 29, 1906.

**ISOSTIGMAR.**—No. 288,362. Photographic lenses included in Class 8. R. and J. Beck, Limited, 68, Cornhill, London, E.C. Manufacturing opticians and photographic dealers. November 28, 1906.

**PEARLOTYPE.**—No. 288,468. Photographs. Thirlwell and Co., 21, Bridge Road, Stockton-on-Tees. Photographers. December 1, 1906.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Drapery in Portraiture.

Not every sitter (says Mr. S. Elwin Neame in "The Photographic News") is suitable for this style of work. The features must be good, the eyes large and expressive. The hair should be dressed in a simple style or allowed to hang loosely over the shoulders. The advantages obtained when the sitter possesses shapely shoulders and arms is very great, and the photographer should give as much consideration to the pose of these members as he gives to the pose of the head. Do not attempt to arrange any drapery until the pose of the sitter gives thorough satisfaction; at the same time remember that every possible rest for the head, body, and arms should be accorded to her. Let us sum up with regard to the principal points of this method of portraiture. They are as follows:—

- (1) The accessories required are so few.
- (2) The long sweeping lines so useful in giving strength and simplicity to a picture are easily obtained.
- (3) By using one long length of drapery continuity of line is assured.
- (4) Repetition of line can be introduced by the folds of the drapery.
- (5) The entire composition being under the control of the operator, the scope for originality is unlimited.

Can any other branch of photography claim to have so many points in its favour and yet suffer such neglect?

### The Straight and the Modified Print.

You will say (says M. Robert Demachy, writing in "The Amateur Photographer") that the practice of intervention is dangerous. Not more so than the use of straight photography for pictorial aims. This may sound paradoxical, but I believe it is just as useless for a man to attempt art through purely mechanical means, as it would be foolish for an astronomer to choose gum-bichromate for printing the chart of the Milky Way. Do not say that Nature being beautiful, and photography being able to reproduce its beauty, therefore photography in Art. This is unsound. Nature is often beautiful, of course, but never artistic *per se*, for there can be no art without the intervention of the artist in the making of the picture. Nature is but a theme for the artist to play upon. Straight photography registers the theme, that is all—and, between ourselves, it registers it indifferently.

### Green Tones on Bromides.

Mr. H. T. Munkman, writing in "Focus," gives the following instructions for obtaining green tones on bromide papers:—

Solution A.	
Potassium ferricyanide .....	6 gms.
Lead nitrate .....	4 gms.
Water .....	up to 100 cc.
Solution B.	
Cobalt chloride .....	10 gms.
Hydrochloric acid .....	30 cc.
Water .....	up to 100 cc.

Immerse the print in Solution A until the image is completely acted upon. This takes a considerable time. The print should next be washed thoroughly, and then treated with Solution B. A bright green image is the result.

ENTRE forms for the annual exhibition of the Worthing Camera Club are now ready, and may be obtained on application to the Hon. Sec., Mr. E. F. H. Crouch, 11, South Street, Worthing. The exhibition will be open from February 25 to 28, the latest date for entries being February 16.

THE Scottish Salon.—The following German and Austrian workers have signified their intention of being represented in the Invitation Section, namely, Messrs. Lützenberg, of Osnabrück; Weingartner, of Leipsic; Müller, of Dresden; Dührkoop, of Hamburg; Erdmann, of Munich; Ehrhardt, of Dresden; and Quedenfeld, of Düsseldorf. We would remind intending exhibitors that January 31 is the latest date for entries for the above exhibition, and that entry forms and full particulars may be obtained from Mr. Robert Milns, Linndate, Potterhill, Paisley.

## New Books.

"The Business Life; or, Straight Talks on Business." By William Gamble. 202 pages; 6½ by 4. London: Sir Isaac Pitman and Sons. 1s.

To-day Messrs. Pitman add to their extensive series of volumes on business topics the above collection of short "talks" by Mr. W. Gamble, the genial manager of the well-known photo-engravers' supply house, Messrs. A. W. Penrose and Co. Many of the chapters have appeared in Messrs. Penrose's monthly, "Process Work," not a few readers of which may have to confess to having skipped them in their eagerness to peruse the more technical pages of that publication. Brought together in a single volume, they are infinitely more fitted for reading, and one can well believe that the publishers are not mistaken in the pressure they put upon Mr. Gamble before he consented to their appearance in book form. Ethics and policy are two large ingredients of the subject matter of these talks. Mr. Gamble preaches as well as advises. We doubt if the sermons are as valuable as the instructions, but there are enough of the latter in the volume to make it of profit to anyone desiring to run "straight" in business on modern lines. We ought to add that the talks are without exception general in character. They are not specially addressed to photo-engravers, otherwise the sermons would have been—but there is no need to say.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, JANUARY 25.

Sutton Photographic Club. "Lantern Slide Making." J. W. S. Burmester.  
Loughton Photographic Society. "Crystal Plates." Mr. Goodwin.  
Cardiff Photographic Society. "An Itching Romance." A Member.  
Photographic Society of Ireland. "Auto-Pastel Papers." Rev. R. E. Vernon Hanson.  
Lyceum Photo. and Art Society. "Rotary Papers."

SATURDAY, JANUARY 26.

Aberdeen Photo. Art Club. "Gum Bichromate."

MONDAY, JANUARY 28.

South London Photographic Society. "Enlarging." R. W. Jeffery.  
Southampton Camera Club. "A Dive into Belgium." Illustrated. W. F. L. Wastell, F.R.P.S.  
Blackburn Camera Club. "Up the Rhine with a Camera." G. Butterworth.  
Oxford Camera Club. "Royal Photographic Society Prize Slides."  
Preston Camera Club. "Collection of Slides."  
Derby Photographic Society. Photographs by R. Dührkoop, by permission of the Proprietors of the B.J. "Print Making."  
Bedford Camera Club. "The Photographic Lens." C. P. Goerz.

TUESDAY, JANUARY 29.

Royal Photographic Society. Technical Meeting. "Animated Photography and the Principles of Duplex Projection." Robert T. Haines. "Some Extensions of Van Helmholtz's Work on Stereo-Photography." T. C. Porter, M.A., D.Sc., F.R.P.S.  
Keighley and District Photographic Association. "Mounts and Mounting." Dickinson.  
Hackney Photographic Society. "Ozobrome." Mr. Manly.  
Holmfirth Photographic Society. "Enlarged Negatives and Colour Photography." Rotary Company.  
Stafford Photographic Society. "Copying by Artificial Light." G. E. Hann.  
Birmingham Photographic Society. "A Tyrolean Valley." James Shaw.  
Darlington Camera Club. "Preparing the Exhibition Print." C. J. Barthorpe.  
Holmfirth Photo. Society. "Enlarged Negatives on 'Rotograph' Negative Paper."  
Acton and Chiswick Polytechnic Photographic Club. "Stereoscopic Photography." C. P. Goerz.  
Hove Camera Club. "Ozobrome." F. J. Phillips.

WEDNESDAY, JANUARY 30.

North Middlesex Photographic Society. Technical Meeting.  
Everton Camera Club. "Irish Art." J. M. Dullehan.  
Borough Polytechnic Photographic Society. "The Principles and Practice of Orthochromatic Photography." A. J. Bull.  
Leicester and Leicestershire Photographic Society. "Development of Negative by the Time Method." Harry Quilter.  
Coventry Photographic Club. "Theory and Practice of Self-Toning Papers." John J. Griffin & Sons.  
Southsea Photographic Society. "Theory and Practice of Self-Toning Papers." John J. Griffin & Sons.  
Croydon Camera Club. "Flower and Fruit Studies." Mr. Seymour.  
Woodford Photographic Society. Auction Sale of Members' Apparatus.  
Edmonton and District Photographic Society. "Home Portraiture." W. Deley.  
Batley and District Photo. Society. "Enlarged Negatives on 'Rotograph' Negative Paper."  
Cowes Camera Club. "What Can be Done with a Hand Camera." C. P. Goerz.

THURSDAY, JANUARY 31.

Richmond Camera Club. "Brittany" J. D. Gibson.  
 Liverpool Amateur Photographic Association. "To Venice and Back with a Hand Camera." R. Child Bayley  
 Hull Photographic Society. "Y.P.U. Slides."  
 Leek Photographic Society. Annual General Meeting.  
 Leedsworth Photographic Society. "Printing by the Ozobrome Process" A. E. Teague.  
 L.C.C. School of Photo-Engraving. "Recent Improvements in Collotype." Alfred Coe.  
 London and Provincial Photographic Association. "Wellington Plates and Papers." A. H. Dunning.  
 Brighton Photo. Society. "Enlarged Negatives on 'Rotograph' Negative Paper"

## PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of members was held on Friday last at the Royal Photographic Society, Russell Square. The full report of the proceedings will appear in our next issue.

## ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, January 22, Mr. J. C. S. Mumery in the chair. Mr. Thomas Bolas, assisted by his son, Master Bernard Bolas, gave the first of a series of demonstrations on early photographic printing processes, commencing with the daguerreotype. He demonstrated the complete production of a picture, commencing with the cleaning of the plate by rubbing over a mixture of rouge and potassium cyanide solution, and afterwards "buffing" the plate with a piece of cotton velvet polishing cloth, such as was obtainable in Clerkenwell. The iodising process then followed, the plate being exposed to the attenuated vapours of iodine in a special box. Mr. Bolas explained that iodine alone imparted the minimum sensitiveness to the plate, and that it was the custom of the old daguerreotypists to afterwards pass the plate through chambers containing mixtures of iodine and bromine and of iodine and chlorine. In this way the highest sensitiveness was obtained, just as in gelatine emulsion the mixture of silver haloids gave the highest speed. The demonstrator explained that the latent image on a daguerreotype plate was instantly destroyed by exposure to the iodine vapour, and that fact was used by the old workers in order to make successive exposures on the same plate if the first was not satisfactory. The latent image was developed by exposing the plate to the vapour of mercury in the mercurial box, although, as the demonstrator pointed out, the exposed daguerreotype could be developed in any of the alkaline developers employed for gelatine plates at the present time. The image obtained in either case was a negative and a positive at the same time, the particles of silver constituting a white mask to the highly polished surface of the daguerreotype plate. On this account a daguerreotype, when held in front of a black surface, appears as an extremely beautiful positive, but when held against a white reflecting surface appears as a negative. Mr. Bolas showed the reversing mirror used by the old daguerreotypists for obtaining a picture without lateral reversal, and he also demonstrated the use of the mirror first employed by Beard for obtaining rapid exposures by daguerreotype, and he instanced the advantages of a mirror over a lens for general photography. He also showed catalogues of the early supply houses for daguerreotype workers, including one of Messrs. Griffin of the year 1852. The early art, he said, of the daguerreotype owed more to Claudet than to anyone else. The latter had an establishment on the site now occupied by the Adelaide Gallery of Messrs. Gatti, and it was he who brought the art of daguerreotype portraiture to its perfection. M. Claudet founded the firm of Claudet and Houghton, now the well-known house of Houghtons, Ltd. An interested audience followed every stage in the demonstration, and a number of questions were asked, and answered by Mr. Bolas, a hearty vote of thanks to whom concluded the proceedings.

CROYDON CAMERA CLUB.—A series of short "chats" on divers photographic matters, by members of the club, resulted in an interesting evening on the 16th inst. Mr. F. J. Terry narrated how, at a pinch, sensitive ortho plates, even rapid panchromatic, might be developed by fire-light. A screen was placed in front of the grate, the diffused light being sufficient to work by. Provided ordinary precautions were observed, he had found, no appreciable "fogging" took place. Mr. J. M. Sellors exhibited a capital home-made enlarging easel, and then drew attention to the recently discussed method of preserving solutions of sodium sulphite from

deterioration by the addition of an acid salt. The formula given by Mr. Welborne Piper in the current B.J. ALMANAC—viz., the addition of one part of potassium metabisulphite to every four parts of the sulphite, had answered well in his hands. It was here pointed out by others that other substances would also, in varying degrees, retard the oxidation of a sulphite solution, notably a group of sugars, hydroquinone, quinine, and mannitol. The last named was the most effective, and a strength of one-tenth per cent. was sufficient. Mr. Sellors then referred to a new ammonium persulphate formula evolved by Mr. H. W. Bennett for reducing negatives. He had found it far more regular and harmonious in its action than the plain solution usually adopted. In the original formula the ounce of 480 grains was given, a most inconvenient basis. Reduced to the "avoir" ounce it would read as follows:—Ammonium persulphate 1 oz., soda sulphite 86 grains, sulphuric acid 43 grains, water to 9 ozs. 1 dr. One part of the stock solution to be taken to 10 parts of water. Mr. S. H. Wratten was next in the list with a new piece of apparatus for dry-binding lantern slides, and a particularly handy contrivance it proved to be. In answer to a query as to who were the makers, Mr. Wratten said he would not unnecessarily occupy the time of the meeting by giving their name. They hailed from the Fatherland. Mr. F. Stokes showed an ingenious method of printing in borders; Mr. Bawcombe, the beautiful and scientific Zeiss "Verant"; and Mr. H. P. C. Harpur, a cleverly thought-out contrivance for making test and other exposures on lantern plates. Dr. Mees, among other things, exhibited several good three-colour prints (Rotary carbon) from negatives taken by him, an excellent "pinatype" by Mr. André Callier of Ghent, and a most graphic method of illustrating the sensitiveness of different types of ortho. plates to spectral colours.

GLOUCESTERSHIRE PHOTOGRAPHIC SOCIETY.—A special meeting of this Society was held on Friday last, January 18, at the Victoria Hall, Bell Lane, Gloucester, when a lantern lecture illustrated by 120 views was delivered by Mr. E. W. Harvey Piper, of London, entitled "An Evening in Westminster Abbey." The story of the Abbey was unfolded, comparison being made with the Cathedral of Gloucester, also a Benedictine foundation dedicated to St. Peter and the two-fold character of the building as monastic church and chapel royal was emphasised. A eulogium of the Abbey's interest to every Englishman was followed by a survey of the entire fabric, its monuments and brasses being criticised or eulogised, and anecdotes or brief biographical summaries given of the personages memorialised. Thus, Queen Elizabeth was described in the sentence: "Intellectual, intelligent, imperious, glorious, vain, vindictive, and vainglorious." The two hours' address, given without the aid of even a half-sheet of notepaper, closed with a visit to the Chapel of the Kings, a glance at the many State ceremonies that had taken place in the Abbey, and a suggestion of the time-long future that yet lay before the venerable edifice. A hearty vote of thanks, proposed by the President, closed the proceedings.

THE PHOTOGRAPHIC CLUB.—Mr. Rogers, of Fuerst Bros., gave a demonstration of the "pinatype" three-colour process on the 16th inst. He first gave a brief description of the theory of the three-colour process in general, and explained recent developments as due to the introduction of the new isocyanine sensitisers, "pinachrome" and "pinacyanol." While allowing that at present the process was not automatically perfect on account of the want of the theoretically perfect printing colours, he claimed that the "pinatype" dyes came nearer than any others to the theoretical standard. In the discussion that followed, Mr. Bridge said he would strongly recommend the beginner to purchase the light-filters necessary rather than attempt to make them himself in the manner described by the lecturer. It was most difficult work, and might discourage him from attempting the process. Some beautiful results done by "pinatype" were passed round by Mr. Beckett, Jun., and were much admired by those present.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—On Monday last Mr. T. Manly gave a demonstration of his new process of carbon printing, by which a large number of carbon prints may be made from an ordinary bromide print. Among the points which Mr. Manly wished to emphasise was the proper hardening of the original bromide print, either by a separate bath of formalin or by a fixing bath containing chrome alum. He did not recommend common alum, as tending to deposit sulphur. He also advised thorough washing of the bro-

mide, as any hypo left in the print was detrimental to subsequent operations, and for the worker to guard against the inclusion of air bells between plate and print when squeezeing. During the evening a number of Ozobromes were made, and passed round for inspection, some being made by transfer to another support, and some made directly on the original bromide, the results in every case being equal to ordinary carbons, without the attendant printing troubles. Mr. Manly showed the great intensification given by re-developing the underlying silver image. In concluding, Mr. Manly said the process had bridged the chasm between silver printing and ordinary carbon printing, the use of large negatives being done away with, and owing to its great simplicity he hoped it would be taken up by every photographer who wished to make permanent prints.

### CATALOGUES AND TRADE NOTICES

Messrs. Reinemann and Co., 7, New Zealand Avenue, Barbican, E.C., inform us that they have secured the sole rights for the United Kingdom of materials for the decorative "Email painting" (imitation of Japanese cloisonné). The list of materials and brushes, etc., will be sent free.

Messrs. Butcher and Sons, Camera House, Farringdon Avenue, E.C., have issued a list supplementary to their general catalogue of 1906. It brings their latest introductions before the customer, and contains particulars of certain revisions of prices. The list is sent free to dealers.

## News and Notes.

THE wall calendar for 1907, which reaches us from Mr. S. H. Fry, the trade enlarger and photographer, this year bears a photograph of the new works, at 5, Highbury Grove, London, N., where the firm's staff recently took up its quarters. The calendar, which Mr. Fry will no doubt send to any genuine professional photographer should be a reminder of the excellent equipment installed at the Frisian establishment, the whole organisation, as we were able to see in the course of a visit paid on its completion, being able to respond to the most exacting demands for trade printing and enlarging.

CHEMISTS' Exhibition.—The thirteenth Chemists' Exhibition, organised by "The British and Colonial Druggist," will be held in the Horticultural Hall, Vincent Square, Westminster, London, S.W., from May 6 to 10, inclusive, and will be open daily from 11 a.m. till 10 p.m. Full particulars can be obtained on application to Mr. A. Norman Flack, Secretary and Manager, "British and Colonial Druggist" Offices, 44, Bishopsgate Without, London, E.C.

A FRENCH Minister's Photograph.—General Picquart (writes the "Telegraph's" Paris correspondent) has been having a mild row with a Parisian photographer, who, by the way, claims to have been a friend of his in evil days, and is now badly repaid. When the general was only a colonel, and was, moreover, in prison, the photographer in question obtained his photograph and exhibited it in his shop. The adversaries of the then colonel promptly smashed the shop windows, and perpetrated other damages. Having suffered with the colonel, the photographer thought it only just that he should rejoice with the general, and when the latter became Minister of War he had several thousand beautiful photographs made and sold in Paris. What was his surprise to receive a letter from General Picquart a few days ago, peremptorily ordering him to stop the sale of these photographs, which the Minister, moreover, qualified as "faked," since he had never posed for them, either before or after he was a general. The photographer admits that General Picquart had never posed for the photographs. They were taken from a carefully made drawing, and their resemblance is perfect. What the photographer laments, however, is not so much the loss of the photographs as the apparent severity towards him of the Minister of War, who, he thinks, is forgetting his friends of former days.

COMBINED Fixing and Hardening Bath.—The Lumière N.A. Co., 4, Bloomsbury Street, London, W.C., write us: "We find the

interest evinced in MM. Lumière's experiments in regard to the composition of a fixing and hardening bath has resulted in a large inquiry for materials necessary for the composition of such a bath. We should be glad if you would make it known that we supply the bath in powder form, under the title of 'Fixolene,' in 1 lb. packets, at 10d., and in boxes containing 176 cartridges, each sufficient for 10 ozs. of solution, at 1s. In addition to this, soda bisulphite lye, which is increasing in demand for addition to fixing baths, and for many other uses, is sold by us in bottles containing 10 ozs. saturated solution, at 8d., or 34 ozs. 1s. 3d.—all these prices, of course, being subject to the usual discount to the trade.

MR. ROBERT T. HAINES, who is on a visit to this country, will, on Tuesday evening next, bring before the Royal Photographic Society a new type of Cinematograph, which he has devised for the purpose of entirely obviating flicker. He is the originator of a good many more instruments and processes than emanate from most inventors. An Irishman by birth, he has lived all his life in New Zealand and Australia, and from the age of thirteen, when he made his own camera and nitrate of silver for the wet collodion process, has

Mr. Robert T. Haines.

studied and practised photography. At an early age he conceived the idea of composite pictures, and suggested experiments which led to good results. One of his earliest inventions is a counting attachment for typewriters by which the number of words and folios is registered as folio after folio is typed. Mr. Haines is also the inventor of a speed indicator for vehicles, a continuous rotary type writer, a potato digger, a selenium photometer, and, among other mechanical appliances, a vacuum washing machine for household use which dispenses with manual labour. In addition to the

duplex cinematograph, which he will discourse upon at Russell Square, his photographic inventions include a new system of cinematograph projection, in which the vocal accompaniment of the pictures are produced by the identical mechanism which actuates the film; and, lastly, a means of transmitting photographs by wire, and even of seeing by wire, the discovery which M. Belin recently announced in our pages.

PHOTO-JEWELLERY.—Messrs. Dorrett and Martin, of 16, Belle Vue Road, Upper Tooting, S.W., are offering a large stock of pendants and other forms of these specialties in dozen lots, assorted according to remittance, which may be from 5d. to £1. The firm offers to refund or exchange any parcel not approved by the purchaser.

DARK-ROOM Safe Lights.—In the current number of "Le Procédé" the liquid cell lamp introduced by Dr. Stenger (E.J. Almanac, p. 693, 1907) is highly recommended, and in addition to the solutions first recommended, the following are given:—

Tartrazine .....	0.5 gms.
Violet dahlia BO, B.A.S.F. ....	0.2 gms.
Water .....	1,000 ccs

filter. This absorbs all light up to  $\lambda$  650, and is suitable for yellow-green ortho plates. For extra rapid and panchromatic plates double the above quantities of dyes should be used, then the light absorbed is up to  $\lambda$  690, and with a 10-c.p. incandescent lamp at a distance of one metre no fog is caused even on panchromatic plates with prolonged development. By replacing the larger quantity of tartrazine by naphthol yellow S (Bayer) 1 gramme, the light is absorbed up to  $\lambda$  685-690. The thickness of the liquid should be 1 in.

## Correspondence.

- \*\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

### ADVERTISING.

To the Editors.

Gentlemen,—As very old advertisers we do not as a rule take any notice of competitive advertising. The public knows, and we all know, that everybody naturally says his productions are superior to all others, but we have always gladly noticed a certain amount of courtesy shown to one another by rival houses in the photographic trade in their competitive trade announcements, and we have attributed this to the connection of photography with those liberal arts which are supposed to soften manners.

It is therefore with some surprise that we notice an advertisement on page 1 of THE BRITISH JOURNAL OF PHOTOGRAPHY SUPPLEMENT of the 18th inst., which warns the public that the "only Genuine Portrait Gaslight Paper" is the particular paper mentioned in the advertisement. The public is also asked to "refuse all papers sold to them as Portrait" except the particular paper referred to.

If this advertisement means anything, it means that Ilford Portrait Gaslight Paper is not Portrait Gaslight Paper, and any such statement is deliberately untrue.

Ilford Portrait Gaslight Paper is specially manufactured with great care for portrait work, and it answers the purpose for which it is manufactured admirably. It need not fear comparison with the paper referred to in the advertisement, or any other, and if the advertisers mean to suggest that they have a particular interest in the word "Portrait," as connected with the photographic trade, we feel sure that the public generally will agree with us that such a claim is altogether preposterous. It would be as reasonable to claim the word "Paper," or the word "Plates."

We are sorry to trouble you with this letter, but we feel that this particular advertisement is so discourteous to us that we think it only right to make an exception to our rule and take some notice of it.—We are, Gentlemen, yours faithfully,  
ILFORD LIMITED.  
Ilford, E., January 18, 1907.

### PORTRAITS BY AMERICAN PROFESSIONALS.

To the Editors.

Gentlemen,—May I be allowed to say that I think all photographers, but specially those who are professionals, are deeply in our debt for the pains you have taken in arranging for the exhibition now on view at your rooms. We should be grateful for its rededersors, which were all interesting and profitable in their way; but none of them could compare in these respects with the present one. And it is much to be hoped that every photographer who possibly can will visit the exhibition, and give it careful study.

Some of the portraits, no doubt, present features hardly worthy of imitation; but, taken as a whole, the show is a most admirable and eminently stimulating one. This, at all events, is the very humble opinion of very gratefully yours,  
WILLIAM GILL.  
Colchester.

### THE USE OF FLAMING SUNLIGHT ARCS IN PORTRAITURE.

To the Editors.

Gentlemen,—I was very interested in finding that my suggestion had been of some service, and also in the valuable experiments which are described under the above heading on page 19, and as I have been making a few experiments in this direction I thought you might be interested in the results.

In the first place it may be advisable to state that I have no interest, commercial or otherwise, in the "Excello" arc lamps. My reason for mentioning this make of lamp was on account of the small quantity of current it used when compared with other enclosed arc lamps. I presume that you will admit that whether the current is used in the resistance, or in the lamp, that it has to be paid for. Therefore, the problem becomes one of 2s. d., and I can assure you that in my district it costs me about 1s. 1d. (say 1s.) to run two 12 amp. enclosed arc lamps for one hour, whilst the same company are running four 6 amp. "Excello" arc lamps for 4d. per hour on a time meter. Whether the light from the "Excello" arc lamps excels or is equal to the light from two ordinary enclosed arc lamps remains to be proved, and I think that the test could only

be conclusive when four "Excello" lamps are hung together in the studio and tested against two ordinary enclosed arc lamps under similar conditions. I can say nothing with regard to the photographic or mechanical efficiency of the "Excello" arc lights, though I am inclined towards the opinion that the light from the four "Excello" lamps will be photographically equal to that from two ordinary enclosed arc lamps from my experiments made on photographing moving figures in the street at night by the light from the lamps.

In your article you state that you used "cored carbons of a similar kind to those used in the 'Excello' lamp, but employed in an ordinary arc lamp," and, further on, you say that the current consumed was "practically equal to ordinary arc." I have, unfortunately, been unable to procure "Excello" carbons of a size suitable for my lamps. The largest I have been able to obtain are similar to the sample I enclose, and though I have attempted to use these carbons in my enclosed arc lamps their low resistance made it impossible for me to make any tests, so that I had to fall back upon the use of the ordinary soft-cored flame carbons for my experiments. May I ask you where such carbons as you used may be obtained?

As you are aware, the quality of the light obtained from the ordinary soft-cored flame carbon varies, even with the same pair of carbons, so that it is practically impossible to obtain uniform conditions for making, or repeating, a set of experiments, and as the light itself fluctuates I have not been able to do more than to arrive at an approximate indication of the speed and colour rendering obtained when comparing ordinary carbons against yellow-flame carbons.

The conditions under which my experiments were made are as follows. The easel of the copying camera was covered with white blotting paper, which was illuminated by two 12 amp. enclosed arc lamps. A Chapman-Jones plate-tester, or sensitometer, was placed in the screen-holder of the camera, so that when the dark-slide shutter was down the sensitometer was placed nearly in contact with the plate. The extension of the camera and the lens stop was adjusted until an exposure of one minute produced a suitable result. The plates were developed for three minutes with the H. and D. pyro soda developer, and they all received the same exposure of one minute under identical conditions, so far as this could be arranged. The length of arc was adjusted to be as nearly as possible the same when using either ordinary, or yellow-flame carbons.

Working under these conditions, a couple of Mawson's Felix plates, bathed with orthochrome T., and exposed whilst wet to the light from ordinary and yellow-flame carbons, respectively, were about the same speed to both violet and yellow light, though the colour rendering is most pronounced when the yellow light was used. Curiously the plates appear to be more sensitive to the red than to yellow, judging from the sensitometer readings, which means that there is apparently more active red light than yellow light in the yellow-flame carbons. I repeated this experiment three times, and whilst I found the speed reading to vary, sometimes the violet light being more rapid than the yellow, the colour sensitiveness remained fairly constant. But it must not be forgotten that the colour rendering may vary, because, speaking from my own experience, I have obtained fairly correct colour rendering, so far as the blue, green, and yellow, are concerned, upon a collodio-bromide plate bathed with silver eoside solution, when working under exceptionally favourable conditions.

As it seems to be quite possible to obtain good results upon bathed plates when used wet, there is no apparent necessity to dry the bathed plates for studio work, for they can be prepared as required for use, and I find that such plates may be conveniently manipulated by the aid of a faint green safe light. After the plates are bathed and washed they are wiped surface dry with a pad of damp cotton wool, or damp wash leather, and placed in the dark slide.

As the light from an "Excello" arc lamp appears to be much yellower in character than that which I obtain from the use of yellow-flame carbons in my arc lamps, it should give, with orthochrome T. bathed plates, a very fair degree of correct colour rendering at a minimum cost for current.—Yours truly,  
Gateshead-on-Tyne.

ARTHUR PAYNE.

[The experiments we described were a comparison of flaming sun-

light carbons and ordinary carbons in the same enclosed arc lamp, approximately the same amount of power being absorbed in each case. The "Excello" lamp was not used in the tests. Power absorbed by the resistance naturally has to be paid for. We pointed out that the meter would register 6 units, though the lamp only took 2½ units. We also mentioned, what is really the important point as regards £ s. d., that with lamps run in series the loss in resistance is very small. Thus two enclosed lamps might have been run in series, the unit only being then absorbed by the resistance.

We do not think wired carbons can be obtained thicker than the sample sent. The carbons employed in our tests were of similar composition. The wire running through the carbon slightly lessens the resistance, and also diminishes the risk of breakage.

If our correspondent will make some actual comparative studio tests, using the "Excello" lamps, we shall be glad to publish the results.—Eds.]

## Commercial & Legal Intelligence.

**WARNING.**—"Since 1903 the prisoner has carried on continuously a system of defrauding advertisers in photographic journals of their goods. His wife is at present doing a term of imprisonment for larceny." This was the record which Inspector Dunn, of the St. Helens police force, presented against William Henry Greenway, at the Quarter Sessions, held at Liverpool, when Greenway pleaded guilty to having stolen a camera and other goods from William Henry Campbell. "Six months' imprisonment" was the verdict.

**SALE of Mercuric Chloride.**—An inquest was held at Southwark, on January 10, by Mr. T. Danford Thomas on the body of Elizabeth Harriett Hardy (35), an inmate of the Bethlehem Royal Asylum. From the evidence it appears that the woman had so far recovered that she was permitted to go out on January 12 to see her relatives. While out she visited the shop of Mr. William Howel, pharmaceutical chemist, 81, High Street, Peckham, and purchased some bichloride of mercury, with which she subsequently poisoned herself in the asylum. In his evidence Mr. Howel said he remembered the deceased coming to his shop, and she appeared to be quite rational. She asked for some bichloride of mercury, saying she required it for photographic purposes. She assured him she only required a small quantity, and that there was no risk, as she thoroughly understood the nature of the poison, having used it before. In answer to the coroner, the witness said that it is not an uncommon poison to sell for the purpose of photography, and he supposed he was asked for it about once a month or oftener. He did not know the deceased, and did not inquire who she was, as he accepted her word that she knew the nature of the poison and had used it before. He made an entry in the customary way, which she signed. Witness was quite aware that bichloride of mercury is in the first part of the Poison Schedule, which was the reason that induced him to get her to sign the poison register. The coroner asked the witness why he served the deceased, as he did not know her, and witness replied that he knew of no reason why he should not. The coroner pointed out that it is set out in the first part of the schedule to the Sale of Poisons Act that it should not be sold unless the seller knows to whom it is being sold and for what purpose it is required. In reply the witness said that he had no knowledge that it is necessary for him to know the buyer. He sold the deceased lady half an ounce, and there was about a quarter of an ounce left in the packet. The admission by the witness that he was not aware that he ought to know the buyer was commented upon by the coroner, who pointed out that Mr. Howel, according to his own account, had infringed the law. The jury returned a verdict of "Suicide while insane."

### NEW COMPANIES.

**BRITISH SOLAR PRINTING CO., LTD.**—Capital £2,000, in £1 shares. Objects: To acquire the business carried on at 66, Pentonville Road, N., by G. B. Kingsley and L. A. Graham, and to carry on the business of printers of bromide and photographic enlargements, etc. The first directors are G. B. Kingsley and L. A. Graham. Registered office, 66, Pentonville Road, N.

## Answers to Correspondents.

- \**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C."* Inattention to this ensures delay.
- \**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*
- \**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

- J. G. Gask, 119, High Street, Deal, Kent. Three Photographs of the Walmer Lifeboat and Crew.
- E. H. Seward, 13, Turton Street, Weymouth. Photograph of Swans and Ciguetas, "The Sweeney, Abbotsbury, Dorset." Photograph of Weymouth Pier with ss. Premier.
- H. W. Hale, 5, Lynn Street, West Hartlepool. Photograph of Combined Teams of the West Hartlepool and Stade Français Rugby Football Clubs.

**ARISTO PAPER.**—I would be pleased if you would inform me (1) what kind of paper is Aristo. Is it only a trade name given to a self-toning paper, and is it difficult to work, and where can it be obtained? (2) Where can I obtain "The Book of Photography," and what is the price of same? What do you think of same as an instruction book of photography?—BROWN.

(1) A collodion P.O.P., largely used by professionals, and made by Kodak, Ltd., Clerkenwell Road, London, E.C. (2) Cassell and Co., La Belle Sauvage, London, E.C. Price 10s. 6d. A very comprehensive text book of modern photography.

**BATHED PLATES.**—Would you please give me particulars of the "bathed plate" mentioned in your paper a few weeks ago with regard to the announcement made by the "Daily Mirror," re stage pictures, etc., as I have to take similar pictures, if I can?—BATHING.

The formula given by Mr. Payne (to whose article we referred in the paragraph) was:—

Water (distilled) .....	400 parts.
Ammonia .....	6 parts.
Orthochrome T. (stock sol. 1:1000) ...	8 parts.

You will see Mr. Payne's article in the B.J. for July 6 last, p. 529, and an abstract of it in the 1907 "Almanac," p. 725.

**INTENSIFICATION STAINS.**—Would you kindly tell me how to remove stains caused by mercurial intensification? I have enclosed the print, and it shows on lady's dress more plainly. I should be very glad if you would help me out of this difficulty.—R. DOIDGE, JR.

It would be easier for us to say, if we saw the negative, but we are afraid there is no remedy for the stains. We should advise you to take as good a print as possible, and after touching out the defects, make a new negative in the camera.

**COPYRIGHT.**—A local firm of photographic dealers are making a feature of enlargements, and I see they have copied one of my photographs. This photograph I have had registered. Should I now demand the withdrawal of the enlargement from show and get a written apology? This photograph has been registered since the large one was made. Still, I presume I have power to act.—AJAX.

You can demand the withdrawal of the enlargement from exhibition.

**BACKING PLATES.**—Can you tell me (1) where backing-paper for preventing halation can be obtained? (2) If it is as effective as ready-backed plates? (3) I am about to expose some very rapid plates by flashlight. Will you give me your opinion on the following developer for such work: (a) Pyro, 1 oz.; citric acid, 1 oz.; soda sulphite, 5 ozs.; water, 50 ozs. (b) Soda carb., 12½ ozs.; water, 50 ozs. Equal parts. This is given in the 1905 "Almanac."—ALBERT MARSHALL.

(1) Any large dealer, such as Fallowfield, Houghton, or Butcher. (2) Not equal to the best backing, in our opinion. (3) The pyro-soda developer contains too much pyro we think.

For flashlight work we should advise a rodinal developer or pyro-metol, as given on page 960 of the 1907 "Almanac."

W. C. T.—(1) We cannot say. (2) Try the Tress Company or Halifax Photographic Company, Halifax. (3) They are quite different. We prefer a hand-fed machine, such as the "Reynaud" or "Hana." (4) Without knowing your circumstances, we may suggest that you mount a dozen negatives together and equalise with tissue paper, then print all at one exposure. This, however, will save time and labour only on very large orders. A machine (see above) will help you much.

A. H.—There are several machines—e.g., the "Reynaud" and the "Hana," which are superior. See the descriptions in the "Almanac." We should advise you not to patent.

COPYRIGHT.—We would take it as a favour if you would give us your opinion on a matter re copyright. The facts are: A gentleman, by invitation, sat to us as a complimentary sitter. We presented him with proofs of his photograph free. Some time afterwards he gave us an order for one dozen cabinets, which we let him have at reduced price. Since then another person has had an enlargement done from the cabinets we supplied. We would like to know your opinion as to whom the copyright really belonged. We may state that these prints were registered by you two or three weeks ago, and the enlargement was done from one of the positions registered.—N.

If the registration was subsequent to the infringement complained of you can only restrain the party from making others. The copyright is yours, but it is wise in such cases where sales are made to persons who did not pay for their sitting in the first instance to obtain an assignment of the copyright to you in writing. It is usual to make this the rule in invitation sittings.

COPYRIGHT.—(1) Am I entitled to sell copies of photographs, the negatives of which have been taken and paid for in the usual way, to anyone who asks for them? (2) By doing so, should I not infringe copyright? (3) A local picture framer has asked me to sell him copies of photographs in place of those he has lost, these copies to be made from negatives used to produce them. He knows I took them. I should have no objection to doing so as he suggests, if I were within my legal rights. But I believe I am not, and awkward questions might be raised if lost photographs were found and returned to my clients, so I have refused. Am I right or wrong?—L. T. J. H.

(1) No. (2) Certainly, you will be infringing the copyright owned by your customer. (3) Right.

C. K.—(1) We do not know it. (2) See an article to appear next week.

PRINTS ON LINEN.—We should esteem it a great favour if you could furnish us, through your paper, with the name of a good firm who print photographs from films on line for d'oyleys, etc.—WEISS AND FOWKE.

We know of no leading firm that quotes for such work. We believe some of the smaller people who do home work for the trade have advertised the printing of d'oyleys. Probably a brief advertisement in our columns would bring you into touch with them. If any address you, care of the Editors, we will send on the letters.

CLEANING ENGRAVINGS.—We shall be obliged if you will kindly inform us how to remove spots on engravings, probably caused by damp or age.—ENGRAVINGS.

This is scarcely a photographic query. However, this may be of use to you. Place the print in a shallow tray and pour cold water over it, and allow it to soak till thoroughly saturated. Pour off the water, and then pour on a solution of chloride of lime (one part liquor calci chlorata of the druggist to forty of water), in this the stains will probably disappear. If not, add a little lemon juice, or increase the proportion of chloride of lime. When the stains have been removed wash well to get rid of all traces of the chlorine. If the engraving is a valuable one we should advise you to place it in the hands of a practical print restorer, as many valuable engravings have been ruined by being tampered with by novices.

GLAZING P.O.P.—I should be glad if you can give me a good cheap recipe for glazing P.O.P., self-toning, or bromide postcards on glass, one that you can be sure of getting off the prints;

also, can they be squeegeed down to glass directly after their final wash?—IGNORAMUS.

Beeswax 20 grains, turpentine 1 oz.

F. P.—1. Pyro-soda is a very unsuitable developer. It is possible that the black spots were caused by pyro dust falling on the paper before exposure. Try metol hydroquinone, and let us know if you have the same trouble. 2. No.

DRY MOUNTANT.—Some time ago I made up a quantity of dry mountant and found it was very good, but I have lost the formula. I can remember there was shellac in it. I am in great trouble, because I use a large quantity of it, and could not afford to buy it ready made.—R. L.

The usual formula is shellac dissolved in methylated spirit, or, better, rectified spirit. Let the spirit dissolve as much as it will by stirring the shellac up at intervals, while the mixture stands in a warm place at a temperature of 70 deg. or 80 deg. Fahr. Then allow to settle, and use the strong solution.

TRANSPARENCY.—The phenomenon is a well-known one, and is known as reversal of the image. It is generally caused by small traces of hypo in the developer, or it can be caused by a gleam of actinic light affecting the plate while developing. Extreme under-exposure and forcing in development is a predisposing cause, so, also, is great over-exposure.

VOLATILE SOLVENT FOR GELATINE.—Is there any volatile solvent that will dissolve gelatine (like water) without altering its general properties? My idea is to secure more rapid drying of a plate after coating with gelatine, than is possible when the ordinary aqueous solution is used.—HANOVERIAN.

The only possible thing to do is to dissolve the gelatine in glacial acetic acid and then gradually add alcohol. A perfectly clear solution can be obtained which will sometimes dry bright, but not always, this depending upon the gelatine used. Whether the acid would act on any substance which is to be used with the gelatine, we cannot, of course, say, as our querist gives us no idea of what the plate is required for.

CELLULOID SURFACE FOR PENDANTS.—How is celluloid affixed to the coloured midgets for pendants?—C. CARR.

The print is painted freely with, or dipped for a moment in, methylated spirit, the celluloid applied, and the two pressed together, preferably with a hot iron.

REDUCING AND INTENSIFYING PLATINOTYPES.—Can you give me a reducer and intensifier for platinotype paper?—C. CARR.

It is not possible to reduce platinotypes without destroying the paper. The best intensifier is—

A.

Sodium formate .....	45 grs.
Water .....	1 oz.

B.

Platinum perchloride .....	10 grs.
Water .....	1 oz.

Add 15 minims of each to 2 oz. of water, and immerse the platinotype till sufficiently intensified, then wash well.

WRATTEN'S FORMULA.—I should be glad if you would kindly put me right re following. In the makers' formulae section of B.J. Almanac, Wratten and Wainwright's is given as follows:—

Metol .....	10 parts	10 grs.
Hydroquinone ...	5 "	5 "
Soda sulphite ...	100 "	100 "
Soda carbonate...	100 "	100 "
Water .....	6,000 "	6,000 minims or 12½ oz.

I work this out as in brackets above, taking 1 grain = 1 minim, but you, in the Almanac, give—

¼ oz. Metol.
55 grs. Hydroquinone.
2½ oz. Soda carbonate.
2½ oz. Soda sulphite.
15 oz. Water.

I should be glad if you would kindly inform me how the difference is made out, as to me it seems that 11 grs. to the ounce of developing agent—and that is what your formula works out at—to be excessive; and yet in my way of working it out it seems rather weak—viz., just over 1 gr. to the ounce, not to mention the enormous amount of sod. carb. and sulphite your formula gives.—V. SERIN.

Our correspondent is perfectly correct in his calculation. Un-

fortunately, a cipher dropped out of our Almanac formula, which should read 150 oz.

**ENLARGING.**—I am thinking of making an enlarging-room of a low shed, the window end of which will face within about 18 ft. of the gable wall of a three-story house. Of course, this would make direct light an impossibility, but would like your opinion whether a reflector would give sufficient light. I have no experience of reflectors, having worked from a window in attic with a sheet of ground glass, but I found the light always strongest at the top (or sky portion), which made enlargements uneven. 1. Would a reflector (on ground floor) give as good illumination as a window in attic? 2. A friend says that as all light would be reflected from sky immediately above, the close proximity of this gable would make no difference to the light. Is this so? 3. What angle should reflector be placed? 4. What size would it need to be to cover up to 15 x 12 negatives? 5. Would not opal glass reflect as much light as a mirror; if the latter, will cheap silvered glass answer? 6. Will a reflector of this kind give even illumination, or is a sheet of ground glass necessary next to negative? There are no high buildings near the sides, only the high gable in front, but the position I want faces north. I should be bothered with sun if either of the other aspects. Thanking you for reply.—**REFLECTOR.**

1. Yes. 2. Certainly. 3. The reflector should be at an angle of 45 deg. 4. The size can be most easily determined by rigging up the apparatus, removing the lens that projects the image, and placing the eye at the aperture. Nothing but the reflector should then be seen. 5. Certainly not; opal would reduce the light considerably, but a silvered mirror should not be used, as it would reflect the clouds, and thus cause patchy illumination. Opal is the best, or else a metal reflector painted with dead white paint. 6. When properly arranged, a reflector of this kind will give even illumination without a ground glass.

A. B. CARR.—The reference was to our contemporary, the "Photo-Beacon," Security Building, Chicago, U.S.A., but you can get similar materials from The Library Bureau, Bloomsbury Street, W.C.

**RETOUCHER.**—It is difficult for us to say, as we know nothing of your work. Your salary is low at present, if you are up to your work. You can judge of wages offered from the advertisements in our pages.

**CARBON TISSUE.**—Could you oblige me by letting me know if there is any process to dry carbon tissues so as to print them at once after they have been sensitised?—**NELSON.**

A fair proportion of alcohol may be used instead of water in making up the sensitising bath.

E. H.—The lamp you have purchased is a satisfactory lamp if you do not object to the peculiar colour it gives to the sitter. We have not had the least difficulty in working the lamp. Have you adhered exactly to the instructions?

**ENLARGEMENT.**—I have to enlarge a plan twice the size. It is now 9 in. square. What size should it be when finished? If I make it 18 in. both ways it will be four times as large.—**GEO WHITFIELD.**

If you require twice the area, the length of each side must be  $\sqrt{18}$ , or 4.15 inches.

**TONING P.O.P.**—For toning postcards (P.O.P. glossy) I have been using bath composed as follows:—

Sulphocyanide of ammonia .....	20 grs.
Chloride of gold .....	2 grs.
Water .....	50 oz.

With this bath I tone from sixty to seventy postcards, according to depth of shadows, etc., and my employer seems to think that I am using too much gold. Before I came to him he had been using an acetate of soda bath, and he seems a little prejudiced against my method of toning, although I am able to produce far superior tones than were possible with the old method. What I want to know is: whether, if I reduce the quantity of sulphocyanide in my bath, I shall be able to tone more postcards, and so save gold? I should have experimented towards this end if I had been sure that altering the proportion of sulphocyanide to gold in my bath would not produce any detrimental effect in the prints. If it has no bad effects, I feel sure that by doing as I suggest I can save the gold considerably.—**CHROMO.**

The tone is likely to be somewhat affected. At present you are getting a very good return for 2 grains of gold. We doubt if you can improve it.

**SODIUM SULPHITE SOLUTION.**—1. On page 751 of the ALMANAC Weissenberger suggests 5 per cent. glycerine as a preservative. Is it 5 per cent. of weight of sulphite, 5 per cent. of weight of water, or 5 per cent. of bulk of water? And what effect would the addition have on development of plates and paper generally, and especially on the time of pyro-soda developer as compared with normal fresh solution?—**Q. S.**

1. 5 grs. of glycerine per 1,000 ccs. of solution. See the full article in our issue of October 19 last. 2. It would retard development.

**THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.**—Will you be good enough to furnish me, through the medium of your journal, the address of the P.P.A.; also, is that the best society to join?—**E. H. LONGKEY.**

89, Albany Street, London, N.W. You cannot do better. It is to your interest in every way.

**AMATEUR PROFESSIONAL.**—The best thing you can do is, as you suggest, to get one of the envelope changers, such as are made by Lizards, of Glasgow, Houghtons, London, Carl Zeiss, London, and Mackenzie-Wishart, Glasgow.

H. G. G. (Leeds).—Will you kindly oblige me with the names of gelatine enamellers to the postcard trade?

Messrs. McCaw, Stevenson, and Orr, Ltd., 32, Shoe Lane, London, E.C.; and Messrs. Strane and Son, of Belfast.

A. G.—We should have liked to have seen a print with the defect you complain of, but in its absence suggest that the articles are lighted too largely from the front. We think a narrow side-lighting will give a better rendering of the bevel.

C. C.—We do not think you would get a paper of the kind you name without a certain amount of gloss. We should say the prints are most likely bromide or gaslight, with a sepia tone obtained by direct development or "sulphide" toning.

A. R. (Tenterden).—Copyright in America can only be secured by photographers making the negatives in the United States or having an establishment there.

**NAVAL MOUNTED HORSE.**—Out of our province. It is a question for your solicitor.

**GLAZING COLLOTTYPES.**—In your issue of December 14, page 999, there is a reply to an inquiry respecting the glazing of collotype prints. As it stands it reads as though the glass was to be first waxed and then coated with gelatine, and the dry print then squeegeed on it. Could you oblige by giving the process more in detail in your next issue?—**J. P. (Scarborough).**

We do not see what further details are necessary. You do not say if you have tried the method given. If you have, we do not see, and you do not say, how you have failed to glaze the prints.

**HOW TO EXHIBIT.**—I have some very good negatives, taken recently (by myself professionally). I should much like to exhibit prints of same. What is the best course for me to take?—**B. B.**

Enter them for the various exhibitions, listed in our issue of the 18th inst., page 47.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The policy which photographers should follow in obtaining payment at the time of sitting was the subject of much debate at the recent meeting of the Professional Photographers' Association. (P. 83.)

The rights of the public and the liabilities of photographers and their making use of the portraits of private individuals are dealt with in an article on the "Law of the Portrait." (P. 80.)

Copyright in works of art has now been made legal in the Isle of Man. (P. 78.)

Treatment of the hair, eyes, and eyelashes is discussed in the article on "Working-up with the Aerograph." (P. 80.)

Platinum residues should be recovered by those employing platinum paper on any reasonable scale. Some notes on the practical methods appear on page 78.

In reference to the divergent views of Mr. Bernard Shaw and Demachy on pictorial photography we publish open letters to these two writers by Mr. F. C. Tilney. (P. 84.)

A review of the "modern photographs" now on view at the New English Art Galleries appears on page 85.

It is proposed to establish a theatre of popular science in London similar to the "Uranias" of Berlin and Vienna. (P. 78.)

## "COLOUR-PHOTOGRAPHY" SUPPLEMENT.

Mr. E. J. Wall contributes some notes on the sensitising of carbon films for three-colour prints, and on the method of cementing the three components. (P. 9.)

The method of reproducing Lippmann interference colour photographs by the three-colour process recently announced by Mr. Herbert E. Ives is given in full on page 10.

Dr. E. König contributes a note on a new method of preparing autotype transparencies. (P. 13.)

The alleged new one-plate process of M. du Hauron leads us to new methods of this kind for direct colour photography. (P. 13.)

## EX CATHEDRA.

### Photography as an Aid to Music.

In a recent lecture to the Photographic Society of Philadelphia, Professor R. Zeckwer gave some interesting details of his experiments on the above subject. His first essay was photographing with the aid of flashlight the correct positions of the fingers and notes in playing particularly difficult runs and passages, both on the piano and organ. The next was to photograph the bodies of singers at the finish of an exhalation and inhalation, and it was thus possible to prove that whereas men usually adopted diaphragmatic or abdominal breathing, women, mainly on account of the non-expansion of their stays, adopted clavicular or chest breathing. There has been, as doubtless many of our readers know, considerable discussion as to the correct manner of breathing in singing, and certain schools adopt one and others another method, some adhering to the natural method, which is so well seen in a baby, that breathes both with the diaphragm and chest. Another important point is, of course, the use of the vocal chords, and some remarkable photographs have been obtained, by the aid of a laryngoscope, of the same in the act of singing.

### The Photography of Sound Waves.

The current theory of sound waves has been accepted by scientists generally for many centuries, but a work has been published in the United States which attempted to prove that the whole theory was fallacious. These views were somewhat generally accepted, with the result that, whilst the old theory was demolished, no new one was advanced in its place. Fortunately the matter was conclusively settled by Professor R. W. Wood, who, by means of an electric spark and a telescope lens, was able to obtain a cinematograph film of the actual sound waves. Later work by the same experimenter has, however, been done by means of the spark of an induction coil which starts the sound wave, and the spark of a Leyden jar passing between two pieces of magnesium ribbon, which illuminates the waves before they pass out of the field of the lens, which was of 5 in. focus. No camera was used, but the plate was merely held in the hand and rapidly moved up and down whilst advancing from left to right, so as to prevent overlapping of the wave images. The results thus obtained have conclusively proved the correctness of the old and universally accepted theory.

### Language by Photography.

Some years ago examination of sound vibrations and the figures produced thereby was considerably facilitated by photography, but the most striking proposal was that of a well-known French philologist, who suggested that photographs in the form of lantern studies should form an essential feature of every lesson in a foreign language, as by this means the pupils

would be able to grasp more readily the correct position of the lips and teeth, which is so important in some sounds. Some excellent results were shown at the time, but so far as we are aware nothing further has been done in the matter. If it were possible to combine these photographic illustrations with the languophone—that is, the phonograph with records of languages—it might be possible to do away with human teachers altogether.

### Business Topics

The report of the meeting of the Professional Photographers' Association, which appears on another page, merits attention for the discussion of one of the most important questions which can enter into a photographer's calculations, namely, the manner in which he obtains from a sitter the charges made for his work. The general tenour of the discussion, initiated by the President of the P.P.A., Mr. Martin Jacolette, shows that the men whose business ability is generally acknowledged, bring to this factor in the success of their affairs all the tact and discretion at their command, and evolve the method which they decide to follow from a strict investigation of the conditions of their establishment. A method which will serve in Regent Street will not necessarily work smoothly in Birmingham, but the essential point which needs to be emphasised is to have a method and stick to it. By doing so, as was pointed out by more than one speaker, the custom of the studio becomes known, and sitters coming for the first time expect to pay at the time of sitting for the simple reason that Mrs. —, who advised them to come, has told them so. What proportion is to be paid and how an outlet is to be left for further business are matters for the photographer to arrange as most expedient for him. Certain it is that a system which, with few exceptions, is rigidly applied will make for a healthy state of business, and will obviate the trouble and uncertainty of collecting accounts.

### Copyright in the Isle of Man.

The Isle of Man, though one of the British Isles, makes its own laws, and hitherto there has been practically no law with regard to copyright. However, on Tuesday of last week, the Legislative Council considered a Bill by which engravings, prints, etc., are given copyright for twenty-eight years, with a penalty of 5s. for every copy infringing the Act. Sculpture, models, and the like, received protection for fourteen years, with a further renewal for fourteen years provided the holder of the copyright be still alive. Paintings, drawings, and photographs are given copyright for the life of the author and for seven years after his death. Musical compositions are also protected, both as to performances and sale, and power is also given for the seizure of pirated music. The Bill received consideration on Tuesday, and on Thursday was passed through all its stages. It will from this be seen that the law with regard to copyright in photographs is generally the same in the Isle of Man as it is in all other parts of the British Empire.

### A Science Theatre for London.

A meeting was held at the Hotel Cecil last week to listen to a statement in recommendation of the organisation of a lecture theatre such as the well-known Berlin "Urania," where a regular programme of illustrated popular science is offered. Sir William Ramsay, who presided, expressed his admiration of the patronage accorded the Berlin institution, and expressed his approval of the scheme on the grounds of the interest in scientific matters which it should create, and of the work it should accomplish in drawing into scientific pursuits persons with a natural aptitude in such directions. It is to be sincerely hoped that the project will not fall to the ground. It already has

reasonable assurance of support from scientific men and scientific bodies, although its sphere of activity will not be limited to science alone. On the occasions when we have visited the Berlin "Urania" the fixtures have been devoted to travel illustrated by photographic transparencies, but the theatre has been the scene of notable demonstrations of colour-photography by Dr. Miethe, for which purposes a complete electric equipment of the projection platform has been most valuable. A similar theatre in London is bound to utilise photography largely, and on this account, if on no other, it is to be hoped that the scheme, which is under the charge of Mr. Albert Wollheim, of 169, Piccadilly, will be brought to a successful issue.

### THE RECOVERY OF PLATINUM RESIDUES.

THE increased price of platinum, and consequently of platinotype paper has one mildly compensating advantage. It should lead the photographer to collect the precious metal which finds its way into the developing solution employed in the platinotype process, and that which is also recoverable from trimmings of undeveloped prints and even from waste prints. The return for the attention to this point of economy is more than it was a year or two ago, before the rise in the price of platinum. We have in our possession a platinum crucible weighing thirty-six grammes, or considerably over one ounce, for which in our student days we paid the sum of two guineas, yet we now see every week in "The Chemical News" the advertisement of a firm of refiners of precious metals who will purchase scrap platinum at the rate of £6 10s. per ounce, and refined platinum, we are told, has to be bought at the rate of £8 10s. per ounce. Hence the value recoverable from old developing solutions becomes much greater for a given bulk than has hitherto been the case, and the return which the careful photographer can obtain in this way may be placed as a small set off against the enhanced price which he has to pay for his sensitive platinum paper. The methods, therefore, which should be followed in depositing the precious metal and bringing it into the state for the refiner to deal with are of considerable interest, and it may be advisable for us to recapitulate the routine which may be employed, although it is, of course, familiar to those who have made a practice of platinum recovery.

The impedimenta required are not numerous:—A two-gallon glass or earthenware jar—a good-sized pickle-jar will do—some zinc, and some spirits of salt, i.e., commercial hydrochloric acid. The manipulation needed for the deposition of the metal is not beyond the powers of those entirely ignorant of chemical operations. Some strips of zinc are placed in the jar and covered with water. A little spirits of salt is then added until the zinc throws off bubbles of gas. The exhausted developer is now thrown in and allowed to stand for about twenty-four hours, in the course of which time a dirty, chalk-like deposit will accumulate at the bottom of the jar, leaving the liquid above it clear and colourless. We will refer to the cause of this change directly, but will now confine ourselves to the practical execution of the process. The clear liquid is poured off—it contains no platinum—and a fresh lot of developer thrown in on the next occasion that an exhausted solution is ready. The whitish mud will not come to any harm in the meantime. The process of reduction goes on while the zinc is being acted upon by the acid, and therefore if the bubbles cease after a fresh batch of developer has been added some further acid should be poured into the mixture. If this does not cause the desired effervescence it will probably be found that the zinc has been entirely exhausted, and needs replenishment in the jar.

The essential part of this process is the reduction of the

platinum salt by the nascent hydrogen, which is produced as a result of the action of the acid upon the zinc. At the same time a good deal of the iron salt in the developer is reduced to the ferrous state and precipitated as ferrous oxalate. The acid only plays the part of a supply of this nascent hydrogen, and therefore any commercial acid such as sulphuric will answer the purpose. Spirits of salt is as cheap and satisfactory as any. Nitric acid, on account of its different character and oxidizing properties, cannot be used. When a sufficient amount of the residue has accumulated the sludge is drawn off, drained from as much water as possible on a linen cloth, and packed for the refiners.

The process of recovering the metal from the clippings of the paper or from trimmings of finished prints is quite different, and the two different kinds of residue should not be mixed, inasmuch as the method employed by the refiner to extract the platinum is different in the two cases, and the mixture of the two would add to the expense of the extraction. The clippings of undeveloped and waste prints are burnt to an ash by setting fire to them in a chamber where there is no great draught, a precaution which is necessary to prevent loss of the particles of reduced metal. A good

receptacle for the prints is an old biscuit-tin in which a row of holes has been made about half-way up. The clippings are placed loosely in the tin and allowed to burn to an ash as completely as possible. The residue obtained in this way is then transferred to a bottle and added to from time to time as fresh batches of paper are treated. There is no objection to the accumulation of the paper and clippings themselves, if room can be spared, and the refiner will as soon treat the latter as the ash obtained in the way above described, but the bulk of the paper is usually an objection, especially if the residues have to be sent by post to the refiner.

The above hints, it may be mentioned, apply equally to the sepia variety of platinotype, and also to prints of any age. It is best to send the residues once a year to the refiner in the case of a large user, and once every two years in the case of a small consumption of the paper. Much of the disappointment which is expressed as to the return in money from residues sent to be extracted might be prevented by bearing in mind the fact that the cost of treating a small batch is very little less than that for a large one.

## WORKING - UP AND COLOURING WITH THE AEROGRAPH.

In the following article is continued a course of instruction in "aerograph" work, two previous instalments of which, dealing chiefly with the acquirement of manipulative skill, have already appeared. The directions for finishing in monochrome which are here given will be followed by similar instruction in "aerograph" work for colouring.

At the risk of repeating much that is trite regarding photograph finishing, the writer will go through the details of finishing in monochrome first, and then the colouring of prints.

It may be desirable in some instances to begin a picture by putting in the background, or some portion of it, to secure the proper conditions for finishing the portrait, but I think a better rule is to do the portrait and finish the background afterwards, in a manner to bring the best effects to the setting off of the figure—the more important part.

### The Average Portrait.

So we will begin with the figure, say, a bust portrait, in black and white. First do a portion of the blackest part of the work; do the collar of the coat, or a portion of the hair, or any full-strength shadow, to get your key, and also get your hand in on a portion of the easier part of the work; then begin strengthening the shadows generally. A good way is to begin at the top of the head and work down; of course, not abruptly, but gradually, as the "aerograph" allows you to do. If you work about in one place a little, and in another place a little, you will not be able to keep your picture so well together.

### Working-up Hair in Portraits.

In doing the hair remember that the camera usually makes the hair look like wire. Keep it soft and in masses—as much as possible—a little sharpness in the high-lights is all that is permissible. Remember also that the reflected lights run through the hair as much as any other part of the picture. Some photograph-finishers work as though they did not know that reflected lights existed; but please remember that they are everywhere in your picture, and if you will accentuate them a little, instead of suppressing them, you will secure better representation of form and more beautiful results.

If you will observe any painting by an old master, or any good reproduction of such a picture, you will notice that the shadows are never brought to a hard edge anywhere, and the

reflected light always accentuated; and if the student will take a little trouble to study nature he will see these reflected lights everywhere.

If you close the fingers of the hand together you will see running along the point of contact, on either side, the reflected light; and the darkest shadow in the crevice between the fingers is bordered by these two lights, the shadow which shows the modelling of the finger being a little distance away from the dark crevice.

Do not shade the hair in any part to a hard edge; look for the reflected lights, and preserve or accentuate them. The "aerograph," from the character of the shadow which it makes, enables you to do this easily. Do not use your darkest colour too freely; keep it for a few points or touches. The low notes, like the highest notes, should not be too prolonged.

You will need to erase some sharp touches in the high-lights of the hair, but leave this until later, when the paper is drier. Now, if your print is a chalk one, you can model the forehead more quickly than it takes to describe it, following the guide print. Remember the reflected lights along the hair and at the disappearing part of the outline if the forehead comes against the background; you can model the cheeks and face generally, or proceed at once to finish the eyes.

### The Eyes.

The eye is such an important part of the portrait that I wish to treat it at some length. First of all it is necessary to understand at least a little of the anatomy of the eye, and a diagram will be useful. The figure is intended to show a vertical section of the eye. I represents the iris, or coloured screen. P the pupil or dark centre. The other parts will be at once recognised. In practically all pictures the illumination, or direct light, comes from above the sitter, and the line L will show in this instance the path of the direct light to the eye; this is seldom directly above; it is usually a little to one side, but the diagram will not permit of showing it otherwise. S is the point

of view of the spectator; in the case of the photograph *S* is the camera. In the normal lighting of an eye, then, there will be a high-light or extremely bright point. If the direct illumination is from a window, this spot will be a small image of the window; it would in that case have a more or less rectangular shape, and would be sharp. The surface of

Fig. 3.

the eyeball is of a highly-polished character, and the reflection will therefore be very bright, unless, as is often the case, it is screened by the eyelashes. Sometimes the sitter is so lighted that the direct light does not fall upon the eye, when the high-light (reflected from some bright object) will be duller.

A portion of this direct light penetrates the outer lens of the eye and illuminates the curtain or iris—the portion of the eye which is blue in a blue eye, or brown in a brown eye. Now, if you want to keep the eye clear and transparent, you must remember to put the greatest illumination of the iris directly opposite the high-light, shading it away strongly to the shadow of the upper lid. The pupil of the eye is always more or less contracted in a photograph, owing to the necessity the photographer is under of placing his sitter in a strong light. It is desirable, therefore, in most portraits, to increase the size of the pupil a little, as would be the case if they were not exposed at the moment of sitting to a strong light—it adds a certain beauty to the eye to enlarge this pupil. This pupil should be dark: give it the full strength of your lamp-black, unless it should be a light blue eye, when it may be softened a little.

### Eyelids and Eyelashes.

Dealing next with the eyelids, the modelling must be carefully done so that the eye will appear round and not flat. The shadow under the upper lid which falls across the pupil is accentuated and made darker by the eyelashes, which in full front, or three-quarter, view of the face are not drawn in, but are represented by this shadow. You will see from the diagram that the upper eyelashes stand out pointing almost directly to the spectator. An additional charm is added to the eye if this shadow be slightly strengthened, and is permissible in the faces of women and children. The top of the lower eyelid will be illuminated, and the drawing must be very slight indeed, the difference in the colour of the flesh and the eyeball constituting the principal difference which will show in the photograph. A little shadow, however, will show under the eyeball beneath the edge of the lid. The eyelashes on the lower lid—turning down—the drawing of them may be indicated slightly. Do not try to make the eye almond shape. The inner corner is lower and more prolonged than the outer corner, and will show a little gland or tissue which catches the light in the corner. This should be drawn true to nature.

Having strengthened the shadows of the eye and eyebrows, the nose and mouth will come in for general treatment. Great care should be used to follow the guide print in drawing the delicate shadows about the mouth and nose, as a little variation in the strength of these shadows will change the expression. Remember that the little reflected lights about the wings of the nose, and on the lips, should be preserved; remember also the larger reflected lights while modelling the chin and the neck.

In finishing the drapery so many conditions prevail which are pre-determined by the photograph, that very little general direction can be given.

[Some hints on vignettes, backgrounds, and one or two other portrait items must remain over until next week.]

## THE LAW OF THE PORTRAIT.

THE following article, by John E. Brady, on "How, When, and Where it is Safe to Print a Portrait without Consent," is from the American journal, "Profitable Advertising," and therefore treats its subject in the light of the law in America, where the legislation as to libel is less rigorous than here. Nevertheless, the cases cited are of the greatest interest to all photographers, as indicating the limits which are justly set to the use of a person's photograph.

At least one doctrine of law, not to mention a considerable number of statutes, may be laid at the door of advertisers who were too aggressive in their methods of bringing their product to the public notice: the doctrine that every individual has a right to enjoy privacy and to be let alone. An examination of the authorities down to the year 1890 would not disclose the mention of such a right. Since that date the argument of its existence has frequently been advanced, but it has remained for the Supreme Court of the State of Georgia (in a case decided recently, which will be referred to later) to declare that such a right does exist.

Prior to that decision it would seem that anyone might, for advertising or other legitimate purposes, make use of the photograph of any individual, whether living or dead, provided that the photograph was not protected by copyright and that its use did not constitute a libel, or involve an invasion of some property or contract right.

### The Use of a Name.

A case which aptly illustrates this proposition was brought up in Michigan, in 1899, and involved the use of the picture and name of Col. John Atkinson, a well-known lawyer and politician of Detroit. Immediately after his death a manufac-

turer of cigars brought out an article which was named the "John Atkinson Cigar," and sought to place it upon the market under a label bearing the name and likeness of Colonel Atkinson. The widow filed a bill in equity to restrain what she deemed an unwarranted and wanton invasion of her rights. While the Court sympathised deeply with the annoyance felt by the complainant, and appreciated "the indelicacy of the man who should join the funeral procession of Col. John Atkinson in a carriage bearing the legend 'The Col. John Atkinson Cigar,'" nevertheless, the injunction asked for was denied on the ground that there had been no actionable wrong, and that there was no good reason for limiting the right to apply a name. The Court argued that names, as a rule, are received at the hands of parents, surnames by inheritance, and Christian names at their will; but that the rule was not invariable for the reason that many names are adopted or assumed by those who bear them; and that the right to apply a name is not exclusive, for the reason that a disreputable person may select the name of the most exemplary for his child, or for his horse, or his dog, or monkey. As for the unauthorised use of the picture, that was held to be one of the ills that, under the law, is without redress.

### The Right of Personal Immunity.

A more recent and familiar case is that of *Roberson v. The Rochester Folding Box Company*. It there appeared that the plaintiff was a young girl, and that one of the defendants, engaged in the general milling business, and in the manufacture and sale of flour, had used her picture without authority, for the purpose of advertising the flour. Over the plaintiff's likeness, in the advertisement complained of, were the words, "Flour of the Family," and below was the name of the manufacturer and the brand of flour making, it must be admitted, a rather noticeable and attractive advertisement. The complaint set forth that 25,000 of these posters were conspicuously displayed in stores, warehouses, and saloons throughout the United States, and that those which had been placed in the vicinity of the plaintiff's residence were recognised by her friends and others who knew her, resulting in her great humiliation and in an illness which confined her to her bed, and compelled her to employ a physician.

The case was decided in favour of the plaintiff by the Appellate Division of the Supreme Court of New York, on the ground that the defendants had violated her right of personal immunity, the right not to be interfered with, to her damage, danger, or discomfort. The Court recognised the fact that the plaintiff had a property right in her features, a right which has been referred to in other cases as the prerogative to control the market of one's own beauty. The defendants carried the case up to the Court of Appeals, where a reversal was obtained and the injunction and damages asked for denied. Hon. Alton B. Parker, who was at that time Chief Justice of the Court of Appeals, delivered the opinion of the Court, and the decision stands for the proposition that in the jurisprudence of the State of New York, the "so-called right of privacy" has found no abiding-place. It is to be noted, however, that the decision was reached by a divided Court, only four of the seven judges voting in favour of the defendants. This decision was heartily condemned by the press, abroad, as well as at home. One prominent journal in New York, spoke of "the amazing opinion of Judge Parker"; while another, by its editorial censure, provoked from one of the judges who coincided with Judge Parker the contribution of an article to a law review in defence of the decision.

### The Position of "Celebrities."

In the case of *Corliss v. Walker*, a widow and her children brought an action in the United States Courts, to enjoin the publication of a biographical sketch of her deceased husband, accompanied by his picture. Relief was eventually denied on ground that Mr. Corliss, who had been an inventor, had become a public character, and had thereby surrendered his right to prevent the reproduction of his photograph. The Court distinctly held that a private individual may prohibit the reproduction of his picture in any form, and recited statesmen, artists, authors, and inventors, who asked for, and desire public recognition, as persons who have waived their right to enjoy privacy.

### The Photographer and Portraits of his Sitters.

While it may or may not be the law, according to the jurisdiction in which the question arises, that an individual has no remedy for, or legal means of preventing the publication of his photographic likeness for trade or other purposes, it is universally held that one is not without redress where he is able to show a property or a contract right in the pictures used. What is meant by a property or contract right may best be illustrated by the cases in which those rights have been adjudicated. The facts of an English case show that a woman had applied to a photographer to have her picture taken, she ordering a certain number, as is usual in such cases. The photographer, after filling the order, made a few copies for his own use. It later came to the knowledge of the woman and her husband that

her pictures were on display in the photographer's shop window, in the form of decorated Christmas cards, bearing the conventional holiday greetings. The matter was placed in the hands of solicitors, and their clerk subsequently purchased one of the cards, which was introduced in evidence at the trial which followed. It was held that, although the plaintiff had no property right in the copies of her picture which the photographer struck off for himself, the right to grant an injunction restraining the further sale of the cards did not depend upon the existence of property, but could be invoked for the purpose of restraining a breach of the implied contract which existed between the parties.

### The Right to Privacy.

The recent Georgia case, of which mention has been made, wherein the right of privacy was upheld, presents a startling example of the extent to which it is possible for an advertiser, piratically inclined, to go. From the report of that case, it appears that the plaintiff's picture was published in an issue of a daily newspaper, printed in Atlanta, in which city the plaintiff resided. Above the picture were the words, "Do it now. The man who did." Placed beside the picture of the plaintiff was the representation of a sickly looking individual, with the inscription, "Do it while you can. The man who didn't." Below the pictures was written, "These two pictures tell their own story," and under the plaintiff's likeness, was a statement to the effect that in his healthy period of life he had been fortunate enough to buy insurance in the company whose name appeared in the advertisement, and that he and his family were enjoying the benefits of an annual dividend upon his paid-up policy. The other person was represented as saying that he had neglected to insure, and had realised his error only when it was too late. The plaintiff's likeness was excellent, and, being easily recognisable by his friends and acquaintances, to say nothing of his enemies, brought him into contempt and ridicule before the world in general. The picture had been used without authority, and the statements in connection with it were absolutely false. The plaintiff, being an artist by profession, claimed that the publication was, therefore, peculiarly offensive to him, and demanded an injunction and a balm of \$25,000. It was accordingly held that the plaintiff's right of privacy had been invaded; that the mere fact that he had become what is known as a public character by the exercise of a profession, which placed him before the public, did not give to everyone the right to print and circulate his picture; and that he was entitled to maintain his action. This decision was also reached on the ground that the publication constituted a libel.

Judge Parker, in his opinion in the *Roberson* case, made the suggestion that the legislature had the power to prohibit the use of pictures and names, and shortly afterward, the legislature of the State of New York passed an Act with that purpose in view. The enactment went into effect in September, 1903, and reads, in part, as follows: "A person, firm, or corporation that uses for advertising purposes, or for the purposes of trade, the name, portrait, or picture of any living person without the written consent of such person first obtained is guilty of misdemeanor." The statute provides further that, where a picture or name is knowingly used for the purposes mentioned, a jury may, in its discretion, award exemplary damages. This statute, it will be noticed, is intended to apply particularly to advertisers.

In an article of this length it is impossible to refer to all the legislative enactments that have been passed concerning advertisers, but it should be observed that such laws do exist in many jurisdictions, notably in California and New York, and that the advertiser is bound at his peril to acquaint himself with the law of the jurisdiction in which he acts.

JOHN E. BRADY.

## HOME - MADE BACKGROUNDS.

THE necessity which at times arises of renovating a background or preparing a new one for a special purpose is one which most photographers have experienced at one time or another, or have possibly regretted their want of experience in such emergencies. It cannot be imagined that any photographer in a fair way of business would find it profitable to make his own backgrounds regularly, but the information conveyed in the following article may nevertheless be of great value to him on occasions:—

Not a few who have essayed to make a plain background, for the first time simple as it seems, have failed in applying the colour in such a way as to obtain an even surface when the work is finished. Now, there is really no great difficulty in the matter if one goes the right way to work, and the few practical hints I shall give should enable anyone to successfully make his own plain backgrounds. There are two or three methods of producing backgrounds, but those in distemper and flaking colour are the most general. The former may be termed a water colour process and the latter an oil colour one. The distemper is the easier of application, and can be done by one person, but is the less durable of the two. The latter, unless the worker is somewhat expert, requires the services of two people in order to obtain a perfectly even coating. By both methods I have made scores of new backgrounds and re-coloured old ones. I shall here assume that a new one is to be made by the distemper method.

### How to Prepare the Material.

At all the large drapers and upholsterers a suitable fabric for our purpose is sold under the name of unbleached sheeting up to eight feet wide, and of any length. It is of different qualities, and prices. The highest quality is unnecessary, but it is advisable not to have a very common one. A frame, of course, is required upon which to strain and fix it. It will be well to have a pretty substantial one. If it be made of inch and quarter or inch and half stuff, and morticed at the corners, it will be very suitable, and a background can be put on both sides of different degrees of darkness. The canvas should be fastened by turning it over the edge of the frame and securing it by tinned tacks. In fastening the canvas to the frame it should not be strained too tightly, as the sizing and colouring causes it to shrink, and much shrinkage would cause the frame to cast, unless it be a very substantial one, so that it would no longer be flat. Before the colour is applied the canvas must be sized in order to keep it on the surface. Two coatings may be necessary unless the fabric is very thin.

Obtain from the oilshop some "double size," and melt it in a saucepan. For the first coat a little water may be added to dilute it. This is applied to the canvas with a whitewash brush. After the first coating is dry the second is applied, undiluted, in the same way as the first. When this is dry all is ready for the colour. This, of course, may be of any tint; grey is the most usual colour, but it is much improved in appearance if a little red be introduced to give it a warm and more cheerful tint.

### Mixing the Distemper.

The pigments usually employed are the common whiting of the oilshops and lamp black. The ordinary lampblack, by reason of its lightness, is difficult to mix with water, therefore it is more convenient to use what is known as "drop black," which mixes easily. In a bucket put a block or two, according to the size of the background, of the whiting and sufficient water to make a thin paste, then add the black, little by little, until the mixture, when intimately mixed, is of a dark grey colour. When this is done rub a little on a piece of brown paper and allow it to dry, to show the colour, for it cannot be judged of from the mixture, as it always dries much lighter than it appears while wet. If it proves too light, more black

must be added, and if two dark more whiting must be mixed in. No definite proportions of white and black can be given as they, necessarily, must depend upon the tint desired. When this is arrived at, a little Venetian red of the oilshop, in powder, if a warm tint is required, is added. This will not materially affect the photographic value of the colour. Water is now added to make the mixture about the consistence of a thick cream. It goes without saying that unless the colours be intimately mixed that streaks of black or red will show when the work is finished.

Next add to the mixture, melted a *hot*, double size in sufficient quantity to produce, when quite cold, a thin tremulous jelly. Here again no definite proportions can be given, inasmuch as the size of the oilshops is so very variable. The actual proportions can only be arrived at by experiment. The best way is to prepare the mixture over night and let it stand till the next morning, then if it is firmer than the condition just mentioned—a thin tremulous jelly—some hot water must be added and the whole allowed to get cold again, when it will be ready for use, as it must be laid on cold. A mistake that some have made in attempting to produce distemper backgrounds is in using the colour warm. Another is in adding too much size. Only just sufficient should be employed to make the colour adhere when dry, and no more. Anything beyond this amount only increases the difficulty of application and the production of satisfactory surface.

### How to Apply the Colour.

For the applications of the colour a large whitewash brush, in good condition, is required. If the worker does not possess such a thing one may sometimes be hired from the oilshop, or from a local house decorator. With a bad or small brush an even coating is next to an impossibility. To get evenness some little knack is necessary, but it is easily acquired. Thoroughly saturate the brush with the colour and lay on thickly, commencing at the top of the background and going right across and working regularly downwards till all is quickly covered. The quicker the work is done when once commenced the better. It is not necessary to be too particular in smoothing the work off as it will, if thickly laid on, dry more even than it looks while wet, but thick ridges must obviously be avoided, so must too thin a coating. In no case must the coating be gone over a second time or marks are certain to show. The chief thing is, to get the whole surface coated before any portion begins to dry.

It has been recommended by some to add a pound or less of treacle (molasses) to the colour in order to retard its drying while being applied, but I have never found it necessary except, perhaps, in summer time, or when the air is unusually dry. At this season the addition is not desirable as in damp weather the coating, if an excess be used, will have a tendency to absorb moisture. If a background has to be done over again, owing to its proving to be too dark or too light, it should be re-sized before the second coating is applied. Should an old background have to be dealt with, which is already thick with colour, it may require two coats of size, in which case the first should be somewhat diluted so as to penetrate the thick colour and render it less abortive of the second coating.

WILLIAM MICHELL.

A SOUTH Suburban Camera Club.—A meeting of amateur photographers was held at 65, High Road, Lee, on January 23, to consider the question of organising a central photographic society for Greenwich, Lewisham, and Deptford. Three delegates attended from the Catford and Forest Hill Photographic Society, and amongst others present were Messrs. Thomas K. Grant, A. E. Bennetto, Charles Stuart, H. A. Robinson, J. F. Ashby and A. Haddon (who was in the chair). A resolution was adopted affirming the desirability of forming such a society, and inviting photographic societies in the district to unite for that purpose. Further resolutions suggested that the prospective society should select headquarters as near as possible to Lewisham Junction, as the most central and accessible position to meet

the convenience of the whole district, and expressed the opinion that the Society's meetings should be held alternately at two or more local centres for the convenience of the members residing in particular localities. The gentlemen above-named were appointed as an organising committee, with Mr. John Nixon, of Ingleside Grove, Blackheath, as hon. secretary pro tem., and it was resolved to invite the Catford and Forest Hill Society and other local camera clubs to nominate representatives to serve on the committee. We understand that the Astronomer Royal and certain of the Observatory staff, Canon Barnes-Lawrence, Mr. Welborne Piper, and a number of well-known amateur photographers living in the neighbourhood, are in sympathy with the scheme.

## THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEMBERS' meeting was held at the Royal Photographers' Society, 66, Russell Square, on Friday, January 18, Mr. Martin Jaolette, president, in the chair.

In opening the discussion on "Payment at the time of sitting," the President said:—After the question of excellence in professional work, the next subject in importance is the adequate remuneration of it, and the means whereby that remuneration may be assured to the photographer. That payment for photographs should be made at the time of sitting has always been recognised as the correct business system, but the method in which the system has been carried out has been subject to considerable variation in detail and many photographers appear to think that there are difficulties in asking for money in advance, which in practice do not arise when the matter is judiciously managed. In my own practice payment is asked for after the customer has left the studio, and not before the sitting. In most cases the customer pays, and in others the account is taken away and a cheque promised. One advantage I find is that as time goes on the friends of those sitters who have paid at the time of sitting have learned that it is expected, and it has, therefore, become understood to be the rule of the establishment, and, consequently, they come prepared to pay. It is also found that decision as to the number of copies required has necessarily to be arrived at at once, and the copies are the sooner in circulation, which I consider of great importance in creating new business, otherwise negatives have waited sometimes for months before the order has been given. Then the collecting of accounts is always a matter of expense and trouble, and sometimes, I am sorry to say, the amounts are not paid without an unpleasant mention of legal proceedings. In some cases, certainly, sitters object to pay before seeing the results, and in these cases I have adopted the plan of giving the sitting and a certain number of finished prints for a stated amount. This plan I have found invaluable in obstinate cases; and to those who find any difficulty I recommend this course to their careful consideration. That the country photographer often is so situated that it is more difficult to make and carry out rules than in London I am aware, but a great many of the difficulties are really not inherent in the system, and may be avoided by a judicious adaptation of the means to suit the circumstances of the particular case. In this connection it is unnecessary to refer to methods which are expected to obtain in the Far West of the operator holding up a card before the sitter upon which is printed a demand for the money, or in holding up the sitter and demanding he cash at the point of the revolver.

The Chairman, in his concluding remarks, said there was doubtless room for considerable difference in practice, and in asking others to give their methods and experience he felt sure the result of the exchange of ideas would be useful to all.

Mr. H. E. Hull said that three years previously he started very much on the same principle as laid down by Mr. Jaolette. He took the trouble to make a list of all the sitters that did not pay, and by tracing the names back he found they practically all originated from one source and from one family connection. None of them paid at the time of sitting, and some never paid at all. It came to his mind that these people had arranged it among themselves. He made it a practice to obtain payment at time of sitting, and if the sitter paid a guinea he was entitled to so many proofs. There were, of course, cases where he did not insist on payment on sitting, owing to his discrimination. He should like to know, however, whether it was better that a customer should be asked to pay before going to the studio or after he came down?

Mr. E. H. Skillmann said it of course depended on the class of business done. He always endeavoured to get the money before his customers sat, and was pretty successful. He thought customers did one another of the rule of the establishment. Of course, in the case of any one he knew, or neighbouring tradespeople, etc., he did not insist upon payment.

Mr. T. C. Turner (Hull) said he thought they were all agreed that this matter really is acted upon by the question of free sittings. Those who had had experience of his studios know that all along they had made it the rule to obtain payment at time of sitting. That system had worked pretty well in North London, where there is a certain kind of clientele; but if they took another neighbourhood, say at Hull, where there were a large number of country

families, business procedure was influenced by the fact that they had to do with people who were demoralised by the system of invitation sittings. It was on that account difficult to get a definite order; but it was advisable that such an order should be obtained before the customer entered the studio. It was easier to obtain payment before customers had their curiosity satisfied by seeing the proofs. The receptionist should be sufficiently careful to get the order before the customer started for the studio, so that his requirements might be known. With regard to the number of proofs submitted an order for half-a-dozen photographs warranted one position, a dozen two positions, and so on, and unless the number of prints required was known before the sitting more negatives would be taken than was warranted by the amount of the actual order. Then, of course, came payment at the time at rates which the customer sees in print and which they cannot get out of. Again, payment at time of sitting was made an advantage to the sitter, one photograph being given over and above the dozen if ordered by prepayment, and customers naturally said: "Oh, we may as well pay now and obtain the advantage." Nearly 70 per cent. of business done is paid for in that way. Unless they were capable of inducing customers to comply the rule receptionists did not earn their salaries. They did not want to pay receptionists 30s., 40s., or 50s. a week merely to behave pleasantly. The crux of the whole thing was payment at time of sitting. It was essential to fighting the pernicious system of invitation sittings that the photographer should make his personality felt. The system was breaking down every day, he was pleased to say, and until it was completely broken down they would always have this bother of getting money at the time of sitting. The men who had held fastest to payment at the time were those who were making money at the present time.

The President said that, in regard to invitation sittings, he had instructed his receptionist to inform sitters that he never gave invitation sittings, as he preferred customers to have the copyright, and his staff were instructed to explain what happens in the case of an invitation sitting.

Mr. Turner said he thought that if they wanted to accentuate their idea of the value of the sitting they should charge so much for the sitting, and make a reduction for duplicates. Another thing, too, it was a splendid lever to secure a larger order. Would not the customer like an extra half-dozen at half-price? He thought photographers did not realise that. The only thing to make a modern business go was to get orders for duplicates. Many photographers seemed to think that the initial order was sufficient. A large amount of his turnover was for duplicates. But, of course, it was only done by charging the proper price in the first instance.

Mr. H. C. Spink (Brighton) said he found his customers only wanted a dozen or couple of dozen, as a rule, and did not want duplicates. He endeavoured to get his sitters to pay a guinea for photographing and then so much for subsequent copies. He came in afterwards by this means.

Mr. Turner said he came in first. He said they had to give him an order in the first instance. His printers would otherwise get an easy time while he would have to put in a lot of time in the studio.

The President thought that one firm's system would not suit another. Still they would learn something from the discussion. He had already done so.

Mr. W. Gill (Colchester) said he did not get quite the class of business that Mr. Turner did. He quoted examples from his price-list, and believed in giving customers the benefit of printed prices. His terms were cash at time of sitting, and compliance with that rule obtained an additional print per dozen. His customers mostly paid cash. He found out how many copies were wanted, the receptionist did her best, and sitters paid when they left the studio. The proofs he sent out finished, but unmounted, with an intimation that all proofs not returned would be charged for. If he missed the cash at time of sitting he generally obtained it at time of order. He was a great believer in the use of printed matter; it was cheap, and did not throw all the work on the receptionist. With every order he got his girls to fill in a form giving the price of extra copies, coloured copies, miniatures, etc. There was nothing invidious about it, and no one could object.

Messrs. R. Fellows Willson, Lang, Sims, C. H. Skillman, and F. Turner gave their views, and in each case payment was required at time of sitting.

The President thought the discussion had been of profit to them all. They had now arrived at as much as was possible to obtain, and he therefore closed the discussion.

#### COMMITTEE MEETING.

Previous to the members' meeting, a meeting of the committee was held. Present: Messrs. F. A. Bridge, H. E. Hull, Martin Jacolette, A. Mackie (hon. secretary), D. Prodger, E. Scamell, Lang Sims (hon. treasurer), R. Fellows Willson, W. Gill (Colchester), H. C. Spink (Brighton), and T. C. Turner (Hull). Mr. Martin Jacolette presided.

The Hon. Treasurer, in reference to the decision at the last meeting to invest £150 in Consols, said he had been advised that there were certain difficulties in that course, and that a more convenient investment would be to place the amount on deposit at the Bank in the joint names of the hon. treasurer and hon. secretary, and had therefore deferred taking action. He asked that the resolution of the committee be rescinded, and that he be empowered to place the amount on deposit at the bank. After discussion this course was agreed to.

The Hon. Secretary reported the joining of four new members since the last committee meeting; also that the January number of the "Circular" had been published and circulated. Six copies had been returned marked "Gone away, no address."

With regard to the proposed new Copyright Bill of the Artistic Copyright Society, the Hon. Secretary reported that the sub-committee appointed to deal with the matter had held two meetings and had carefully considered the draft Bill and its bearing upon photography. A conference had now been arranged with representatives of the A.C.S., at which it was hoped an agreement would be arrived at which would preserve the copyright in photographs from the fate it would meet with under the provisions of the Bill in its present form.

A discussion took place upon means to be adopted by the Association to protect photographers and the public from the fraudulent practices of canvassers for free enlargements, and other frauds of a similar nature.

The meeting was then constituted special in accordance with the rules for the nomination of a president and twenty-four members of committee to serve for the ensuing year.

After the formal business, the question of a committee dinner was discussed. It was agreed to hold a dinner on similar lines to those of the two previous years, on Thursday, March 7, the evening before the annual general meeting, and that Messrs. A. Ellis, Lang Sims, and the President be constituted a sub-committee to make the necessary arrangements.

#### THE TENDENCY OF ENGLISH PICTORIAL PHOTOGRAPHY.

In reference to the views expressed by M. Demachy that photographic characteristics are anti-artistic characteristics, views, to which we referred in our issue of January 4, a full translation of M. Demachy's article appears in "The Amateur Photographer" for Tuesday last, where also Mr. G. Bernard Shaw comments on M. Demachy's position. The following two letters to the disputants are sent to us by Mr. F. C. Tilney:—

AN OPEN LETTER TO G.

BERNARD SHAW, ESQ.

MY DEAR SIR,—Your little bout with M. Demachy is such rich entertainment that I cannot resist a dig at my typewriter to say how much your views upon pure photography will be appreciated by artists, and with what dignified reticence your views upon painting will be received by the same community. With a full knowledge of my shameless intrepidity, I put myself in the place of spokesman. Quoting M. Demachy in respect to methods of art, which are said to be incontestably superior to photography, you say, "Name those methods.

AN OPEN LETTER TO M. ROBERT

DEMACHY.

MY DEAR SIR,—Why do you distress yourself about the opinions of the English critics? They mean well enough. They are always delighted with your work. No one in his senses would debar himself the pleasure of contemplating your works of art because he happened to note that photography had "stepped out" of them. We all admit your right to give us beautiful pictures by any methods you choose. Please go on doing so. The real point is, and I think you have perhaps missed it, that those who have the advancement of photo-

graphy at heart, such as Mr. Bernard Shaw and others who hold a brief for what are called "straight" prints, do not quite see how your beautiful work reflect any credit upon photography at all. The credit is all to your own artistry. These pure souls, who put mathematical accuracy among the virtues, cannot see virtue in things that are not mathematically accurate. Hence they do not like pictures of places that they cannot run with to the place of inception and compare each item satisfactorily with its prototype in the scene. *Entre nous*, they are barbarians! Perhaps they have an inkling of this fact themselves, and seek to rise into artistic culture by the greasy pole of pure photography. Certainly, one of them has said: "Our only hope, then, is in evolution. We must replace the man by the superman." In fact, they want to breed the super-photographer. To this end you do not help them, since your methods are only an overwhelming stultification of photography uncontrolled. When you give out that the photographic character is an anti-artistic character, they very naturally say, "What's this?" and dash off fragmentary letters to the papers. If it really is anti-artistic they are done for—an eventuality that they would avoid at any cost. For my own part, I delight to count myself one of your obscure followers when I average up the merit of all the pure prints I see from one year to another. But should we go so far as to say that we never saw a straight print that was lovely? You and I, dear Sir, know more than and I, dear Sir, know more than one pure photographer, whose prints mark him undoubtedly as one of the initiated; as one, even, of the true-born. The work of such is only imitative, certainly, and, as such, it is not art of the highest planes; but its character is not anti-artistic; and, further, it points to possibilities of evolution along this imitative line that I, for one, should like to see encouraged.

You have been at some pains to prove that all the control you exercise, from negative to finished print, is done in your right as a photographer. I think it might be as well argued that it is exercised in your right as an artist to whom the initial photographic stages have not given satisfaction. When the pure

What are they? I deny their existence." Of course you do! You deny the existence of most things that we treasure, and we treasure you in consequence, for we know that the things *do* exist, or else you would not be able to knock them down, and your game of nine-pins is too delightful to miss. You ask for the name of some of the particular nine-pins under discussion. Here are a few: Elimination, suppression, enrichment of tone, introduction of accent, modification of composition, and, greatest of all, the catching of the artist's mood as he looks at nature. In your capacity of musical critic you would not dare to deny these things to music; we give you credit for logic enough to grant them in painting also.

What you claim as the highest aim of photography is the mere imitation of natural facts, and there I am with you entirely, whilst I add that such an aim is not nearly high enough for painting. That is why we can stand things from Corot that we would not stand for a moment from any pure photographer whose only aim is to reflect nature as in a mirror, to borrow the metaphor of a recent correspondent in the "Daily Chronicle." Imitation is not art: it is mere mimicry. If that were not so, you would have to put a student's still-life study above the masterpieces of the world. No doubt you do. But there is a higher truth than truth of fact for fact's sake. It is the truth that is eloquent of a message coming from nature to an artist, and handed on from the artist to all who will hear. It is not a message of topography, physiognomy, architecture, but of what those things have whispered to the artist, who alone can write it down, and hand it on. If you want the best record of soil and vegetation, of skin and bone, of stones and mortar, the camera will give it you; but don't call it art when you've got it. No one denies that these externals may be beautiful in themselves, and are worth recording and treasuring as we treasure bits of spar and pretty flowers. When they are recorded with the exquisite judgment and subtle appreciation of an F. H. Evans, photography is lifted to its highest glorification. Here it surpasses painting, simply because painting is not at its best when imitating the bodies of things, but

when it concerns itself with the spirits of them. Hence its methods are incontestably superior to photography. *Quod erat demonstrandum.* You can't really suppose, my dear Sir, that Rossetti and Ruskin were keenly interested in photography because they thought its methods incontestably superior to painting.

Both you and M. Demachy appear to agree as to photography having no limitations. Certainly, there seems to be no limitations to the methods of our clever French neighbour; but then they are not photographic methods. As to yourself, my dear Sir, whence, pray, the outcry you raise but from the wounds of your bruised body battered against those very inexorable limitations? Do not your own attempts —

I regret that an urgent appointment with some students of mine compels me to break off at this thrilling point. But I will just stay to sign myself—Yours in arms to separate painters from photographers in this discussion.

F. C. TILNEY.

photographer feels such dissatisfaction he does not preserve his work. You bring it through, by virtue of certain calculative processes which carry the thing along lines quite different from those of the initial stages. What is the difference in this case between chemicals and a painter's paraphernalia? An essential one. The fact remains, my dear Sir, that you are not a photographer, you are an artist making use of photographers' paraphernalia.

Whilst you continue to assert that your methods are photographic, you are mixing things up. The phrase, "artistic photography" is almost a solecism. Good photography is in no need of control and manipulation, yet those are the things that every other photographic frog bursts himself with. It follows that half the photographs would be better without control and manipulation, and this is Mr. Shaw's great and sound point.—I beg to subscribe myself, dear Sir, your admiring disputant,

F. C. TILNEY.

## Exhibitions.

### MODERN PHOTOGRAPHS AT THE NEW ENGLISH ART GALLERIES.

To any who are unacquainted with the peculiar qualities and the exalted aims of the modern artistic school of photography, the exhibition now open at 67a, New Bond Street will no doubt be of the highest interest and instructive value. To those, however, who know the work of Craig Annan, Coburn, Holland Day, Demachy, Mrs. Kasebier, the Baron de Meyer, and Puyo, the exhibition is not freshly informing. Most people who take an interest in pictorial photography have seen the bulk of the exhibits before, and it is to be presumed that the inception of the show is due to a desire for a special appeal to the outside public who have escaped previous exhibitions.

It is quite unnecessary to say that the collection of prints is a particularly art-y one. Its very housing upon the walls of the most advanced of art clubs gives it a sort of proud exclusiveness. By the way, those walls have a truly attic simplicity, being approached by a sort of slum staircase. But the place is bright and the walls are clapped, and the prints are stylishly mounted, and the catalogue is easy," and the Bernard Shavian shocks (which the photographers have coolly appropriated to make folk think that this is the style of photography which inspires the oracle, whereas really it's the style of thing that he will have none of) are of high frequency.

Six of the exhibitors send twenty works each, and the seventh, Puyo, sends but eight. If all had sent eight—the best eight—the show would have been more worth the shilling toll that is levied upon all who would ascend this Avenus.

The pictures of J. Craig Annan are the most steady in aim, and the most chastened in style. We wonder that so photographic a work as the "Portrait of Mrs. C." is allowed in this company. Of A. L. Coburn's work the finest are "Setubal," the "Rudder," and "London Bridge." F. Holland Day's prints are all dated, as though he were an imitatable "old master." It must be admitted that they wear well, for after an absence of three or four years one turns to them with all the old interest revived. The gum prints of M. Demachy are always enjoyable, and we shall never tire of the "photographic character" of such good things as "Montmartre."

In the case of Mrs. Kasebier a half dozen stand out from her score being fine things, and two of them are excellently fine—namely,

"The Silhouette" and "The Manger." The Baron de Meyer has chiefly filled his space with glass jam-pots holding gawky culled blossoms. One of these prints is indeed but the photograph of the shadow cast by two or three chrysanthemums. It is hard to imagine pictorial motive and incentive in worse straits. His six portraits are more worthy things, especially "Mrs. Kasebier," "Mrs. Koehler," and "Baroness de Meyer." The works that M. Puyo sends add nothing to his present reputation. One which appeared to have a cloud of flying fishes in the air turned out to be a picture of snow-covered hills with bits of dark rock showing through.

If the lay press, taking this little group of moderns on trust, and not as they find them, has given furtherance and publicity to pictorial photography, as one or two undoubtedly have, then we cannot but be grateful to the promoters of the show. We wish them both cash and kudos of their venture, which lasts until February 9.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following patents were applied for between January 14 and 19:—

PAPERS.—No. 993. Process for preparing paper for photographic purposes. York Schwartz, 77, Chancery Lane, London.

FINISHING PHOTOGRAPHS.—No. 1,157. Machine for preparing glass or other plates and applying thereto photographic prints in the process of finishing. Charles Rubie Neve, Belmont, Spencer Road, Wealdstone, Middlesex.

DAYLIGHT DEVELOPMENT.—No. 1,229. Improvements in and relating to the daylight development of photographic plates and films. George Wishart, 96, Buchanan Street, Glasgow.

PRINTING DEVICE.—No. 1,359. New or improved photographic printing device, particularly applicable for use in the duplication of drawings. Charles Jennings Hillman, 149, Strand, London.

DAYLIGHT DEVELOPING, ETC.—No. 1,404. Improvements in and relating to the daylight insertion and exposure in the camera of photographic dry plates or films, also the daylight developing of same, and combined appliances therefor. George Wishart and Frederick Mackenzie, 96, Buchanan Street, Glasgow.

FILMS.—No. 1,454. Improvements in the manufacture of films for photographic and other purposes. John Henry Smith, Cun House, Surrey Street, London.

SHUTTERS.—No. 1,468. Improvements in curtain-shutters for photographic cameras. Optische Anstalt C. P. Goerz, Akt.-Ges., 31, Bedford Street, Strand, London.

### COMPLETE SPECIFICATIONS.

The following complete specification is open to public inspection before acceptance under the Patents Act, 1901:—

COLOUR PHOTOGRAPHY.—No. 716, 1906. Process for reproducing multi-colour photographs by means of one negative. C. L. A. Brasseur.

### New Trade Names.

COLO.—No. 286,153. Chemical substances used in manufactures, photography or philosophical research and anti-corrosives. George Nelson, Dale, and Co., Limited, Emscote Works, Wharf Street, Warwick. Manufacturers of gelatine. September 13, 1906.

FAIRY.—No. 286,156. Chemical substances used in manufactures, photography or philosophical research and anti-corrosives. George Nelson, Dale, and Co., Limited, Emscote Works, Wharf Street, Warwick. Manufacturers of gelatine. September 13, 1906.

ISOGINE.—No. 286,159. Chemical substances used in manufactures, photography or philosophical research and anti-corrosives. George Nelson, Dale, and Co., Limited, Emscote Works, Wharf Street, Warwick. Manufacturers of gelatine. September 13, 1906.

RADITE.—No. 287,638. A chemical substance used in manufactures, photography or philosophical research. Masters Monroe, trading as the Radite Company, 190, Vauxhall Bridge Road, London, S.W. Engineer. November 6, 1906.

SATRAPOL.—No. 289,125. Chemical substances used in manufac-

tures, photography or philosophical research. Chemische Fabrik auf Actien (vorm E. Schering), 170, Mullerstrasse, Berlin, Germany. Manufacturers. December 27, 1906. Address for service within the United Kingdom is c/o Carpmal and Co., 24, Southampton Buildings, London, W.C.

RAJAR.—No. 287,481. Photographic sensitised paper. Rajar, Ltd., Town Lane, Mobberley, Cheshire. Manufacturers of photographic materials and apparatus. November 1, 1906.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Ozobrome.

The working bath dissolves a little gelatine when used (writes Mr. J. H. Wilson in "The Photographic Monthly"), but will keep a long time if Mr. Manly's hint be taken about the addition of alum. He recommends that from 40 to 80 minims of a 5 per cent. solution be added for each four ounces of concentrated solution contained in the old working bath just before it is used. A statement to the effect that ordinary carbon tissue is unsuited to the ozobrome process is a direct challenge to the perversity of human nature, at any rate, in individuals like myself who have an unbelieving habit of making tests. I consequently wasted much time and about a square foot of carbon tissue in the attempt to disprove it. I found that, while it is easy to get an ozobrome of a sort in this way, yet I could not get anything like such a good one as from "the pigment plaster" and the same original, and this is owing, I believe, to the difference in the proportion of gelatine contained in the two.

### Shaw on Demachy.

This outburst of our friend Demachy (writes Mr. G. Bernard Shaw in Tuesday's "Amateur Photographer," in reference to M. Demachy's recent description of photographic characteristics as "anti-artistic") is pure *lèse-photography*. What is all this about "the photographic character being an anti-artistic character"? About "methods of art which are incontestably superior to photography"? Name those methods. What are they? I deny their existence. I affirm the enormous superiority of photography to every other known method of graphic art that aims at depicting the aspects and moods of Nature in monochrome. I say that a photographer imitating the work of a draughtsman is like a man imitating the noises of a barnyard; he may do it very cleverly, but it is an unpardonable condescension all the same. Also, he is substituting an easy, limited, and exhausted process for a difficult one which has never yet been pushed to the limit of its possibilities.

Mr. Shaw breaks off his note in characteristic fashion:—

"I regret that an urgent appointment at the Court Theatre compels me to break off at this thrilling point."

### A Distance Table for Flashlight.

The following table, given in the "Photographic News" of last week, is advanced as a guide for the correct amount of pure magnesium necessary for lighting a portrait at certain distances, using stop *f*/11 and an extra rapid plate:—

Distance of Light from Subject.	Grains of Magnesium required.
10 feet.	20 grains.
15 "	45 "
20 "	80 "
25 "	125 "
30 "	180 "
35 "	245 "
40 "	320 "
45 "	405 "
50 "	500 "

For ascertaining the quantity of light necessary for any other distance it should be remembered that here the value of the illuminant varies conversely as the square of its distance. Taking five grains of powder, therefore, as sufficient to light a portrait at five feet distance (five feet is much too near, however, for most practical work, as the lighting would be very harsh), it is easy to ascertain any other amount necessary for any given distance.

## Dew Apparatus, &c.

The Kodak Paper Developing Machine Made by Kodak, Limited  
57-61, Clerkenwell Road, London, E.C.

To save the fingers of the photographer from contact with the developing solution is, we take it, the chief aim of the Kodak Company in producing this piece of apparatus, and admirably they have achieved it. The machine has other points to its credit, but this we should put first. The exposed bromide or gaslight paper need not be touched from the time it leaves the worker's hand until ejected from the machine into a dish of water, as shown in the second figure. Developer having been poured into the well of the machine, one end of the print is inserted in the slot of the drum

Fig. 1.

(shown in Fig. 1), and the drum rotated. The print is thus drawn evenly through and through the developer, its progress being observed as it passes on the upper side, where, if need be, it can be allowed to rest. All that is necessary to transfer it to the wash water or the fixing bath is to reverse the handle, when the print is lifted from the drum and discharged over the hinged "shoot" on the front of the apparatus into its appointed receptacle. We imagine that those who are unable to employ metal owing to the effect it has upon the fingers, will gladly welcome this piece of apparatus; but many more than those afflicted with this personal idiosyncrasy

Fig. 2.

crasy should favour the addition of the machine to the equipment of their dark-rooms on account of the even and regular action of the developer and the entire absence of mess. The introduction of the machine marks another step made by the Kodak Company in making every photographic operation fit almost for the drawing-room or boudoir.

The developing machine is made in shining nickelled metal, and in appearance is so handsome that the task of the dealer—and particularly of him who can exhibit it in action—in selling it should be the easiest imaginable. The instrument takes prints up to about 10 x 5 inches, and costs £1 4s.

The Minimum Pamos 2½ x 3½ Folding Camera. Made by Carl Zeiss, Jena, and 29, Margaret Street, London, W.

In issuing a smaller pattern of the Pamos camera, which we reviewed almost exactly a year ago, the eminent Zeiss "Stiftung," of Jena, have embodied several new features which still further add to the usefulness of the instrument in practical work. In the first place the focal plane shutter in self-capping—that is to say, the slit is closed during the winding of the shutter and does not reach the particular width for which it is set until it is released. The gain in convenience to users of roll-film does not require to be pointed out, but it may be said that this added convenience of the focal-plane shutter is attained without sacrificing the facilities of the shutter in other respects; and, as in the case of that fitted to the cameras

already submitted to us, the adjustment of width of slit is done entirely from the winding key, and is made either before or after winding. The shutter is fitted with one tension only, the speeds, from 1/10 to 1/750, being obtained by alteration of the slit. The shutter also opens to the full size of the plate for time exposures.

In other respects the camera is excellently made—in fact, it is difficult to think of a more efficient combination of strength, lightness, and utility—and in detail and general design is admirably adapted to be the companion of a tourist photographer, who need not fear to take it into any part of the world.

The camera takes a  $3\frac{1}{2} \times 2\frac{1}{2}$  picture, is fitted with a Tessar  $f/6.3$  of 11.2 cm. focal length, and with three double dark slides and leather case costs £13 5s.

The Deckel "Compound" Shutter, 1907 Model. Sold by A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London, E.C.

In the model of this shutter improvements have been made which make for accuracy of working and convenience in use. The shutter is now made throughout of magnalium (black bronzed and inconspicuous), and weighs just over three ounces, the three plates of the diaphragm opening being very light indeed, and thus aiding the proper working of the shutter. There are the customary time, bulb, and instantaneous adjustments, the figures for which are engraved, not only on the face of the shutter, but on the upper rim of the central dial plate, so that a change can be made by the operator from behind the camera without leaning over to

examine the face of the dial. The shutter is made in six sizes, interchangeable with the  $5 \times 4$  and  $8 \times 5$ , "Unicum" and "Auto" shutters, so that existing lenses fitted with these shutters can have a new "Compound" attached without any alteration beyond the engraving of the diaphragm plate. We are glad to add to this the fact that for an additional sixpence Messrs. Staley supply a card of speeds for the shutter from tests made by themselves, an offer which should be proof of their satisfaction with the incidence of the marked and actual speeds.

THE Boardman Arc Lamp.—In reference to the new lamp of the Boardman Co., noticed in our issue of January 18, we would like to be allowed to supply an omission. The lamp was submitted to us in notice by Messrs. W. Watson and Sons, 313, High Holborn, W.C.,

who are the agents for it. Messrs. Watson will be pleased to answer any inquiries as to the lamps and to quote for complete installations for any given purpose. We are all the more glad to add this announcement to the technical particulars published a fortnight ago, since many of Messrs. Watson's customers will be glad to know that the old-established Holborn firm is watching their interests in the matter of artificial light.

The Imperial Exposure Reckoner, issued by the Imperial Dry Plate Company, Limited, Cricklewood, N.W., reaches us in a revised form. The table of speeds of the Company's plates, for which the "reckoner" is intended, has been brought into line with present manufacture, and, at the same time, the form of the reckoner is greatly improved. As now produced, the publication is a stiff folder measuring  $2\frac{3}{4} \times 4\frac{1}{2}$  inches, and carried comfortably in the waistcoat pocket. The scales are easily legible, and provide for the widest range of conditions in outdoor and indoor photography on the seven leading brands of "Imperial" plates. The "Reckoner" is strongly made in cloth, and sells at one shilling.

MOTORING Portraits.—Messrs. W. H. Redshaw and Son, Bourne, Lincs., have introduced a new series of accessories in the shape of imitation motor cars, which should be popular with photographic businesses where sitters appreciate surroundings which are foreign to their customary daily routine. The motor car accessories are supplied in two styles, the larger capable of seating three persons, and costing with seat and wheel complete, in flatted oil, £5 5s.; the smaller, showing the front of a car, and seating two persons, costs 7s.; or 6s. without seat. Messrs. Redshaw and Son will doubtless send a photograph illustrating the accessory in use to genuine photographers who make application to them.

## New Materials.

"Criterion" Rough Matt Bromide Paper. Made by the Birmingham Photographic Co., Stechford, Birmingham.

A new variety of bromide paper has been added to the series of "Criterion" papers by the introduction of this "rough matt," which is not rough and not matt, but something between the two, which it is useless to attempt to describe, but which, we should say, might be used for all the work which is usually done on the finest matt, if the photographer feels that his sitters can stand a slight move away from the minute detail of the glossy and semi-matt papers. In other respects the paper, in our hands, has shown itself possessed of the good qualities looked for in a modern bromide paper, and is supplied in all the usual sizes of sheet and package.

Mattos Papers, Vellum, Silk, and Wood. Made by Mattos, Ltd., 36, Arundel Square, Barnsbury, London, N.

We have recently had the opportunity of employing a supply of these sensitive materials, manufactured by the Mattos Co. for those of their customers who desire effects of a broader character than is obtainable on the rather fine matt surface of the standard brand of the No. 1 paper. The Nos. 2 and 3 papers are "Smooth Rough" and "Half Rough," the latter a rougher surface than the former. This choice of papers should satisfy photographers who are putting something distinctive before their customers, but the Mattos Co., with veritable prodigality of resource, issue also other special paper, Japanese vellum, linen, silk, satin, and wood, all sensitised by their process and all treated in identically the same way as the Mattos paper with which many of our readers are doubtless conversant. Our experience of these materials is not an extensive one, we will admit, but is sufficient to show us the ease with which a great variety of effects are obtainable without altering the *modus operandi* as regards toning and the other operations, save only in the case of the sensitised wood, that sufficient time must be allowed for proper fixation and for washing out the hypo. The tone of a print on wood, also, is warmer than that of one similarly made on paper. We commend a trial of these materials to those photographers who can place a novel and fairly high-priced type of print before their customers with a reasonable prospect of profit. The prices of the special sensitive media are higher than those of the regular paper, but the Mattos Co. supply in small packets, thus permitting of a tentative use of them at a small outlay.

A specimen of the "Prima" enlargements of Mr. H. Holden, 10, London Street, Paddington, W., is submitted to us by the maker, and is a piece of bromide work which we can commend for its fine lustrous quality. Mr. Holden works by daylight, and finds that he thus needs to put much less "finishing" on enlargements and that the retouching on the negative is agreeably rendered. His claims are certainly borne out in the example before us.

### CATALOGUES AND TRADE NOTICES

Some specimens of effective printing reach us from Messrs. Edwin Osborne and Co., 26, Red Lion Square, W.C., and known to all photographers as a supply house of mounts and other studio stationery. The examples show Messrs. Osborne to be successfully producing price lists and booklets which photographers may distribute with profit.

Messrs. W. Watson and Sons, of 313, High Holborn, London, W.C., send us their latest list of second-hand apparatus, a copy of which they will forward to any of our readers on application. The list included, amongst a variety of other articles, a large assortment of high-class cameras and lenses at greatly reduced prices, and we would advise those who intend adding to their photographic outfit for the coming season to obtain Messrs. Watson's list, or give them a call at the above address.

Bargains in enlargers are specified in a circular issued by Mr. W. Hume, 1, Lothian Street, Edinburgh, the well-known maker of enlarging apparatus. Mr. Hume is revising his series of enlargers, and in consequence offers a number of instruments, suitable for amateur and professional use, at about half the list prices. The circular should repay perusal by those in want of a reliable enlarging lantern for oil, gas, or limelight.

An album of celebrities has been issued by Messrs. Marion and Co., 22 and 23, Soho Square, W., as a reminder of the leading houses who use Marion plates in their regular business. The album includes portraits of the King, Lord Curzon, Mr. Chamberlain, Mr. Haldane, Lord Kitchener, Sir Henry Irving, and includes the prices of and formulae for the various brands of the firm's plates. It is sent free on application.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### FRIDAY, FEBRUARY 1.

Sutton Photographic Club. "Modern Methods of Mounting." Hector Maclean.  
Aberdeen Photo. Art Club. Exhibition and Social Evening.  
Chester Society of Natural Science. "What Can be Done with a Hand Camera." C. P. Goerz.  
West London Photographic Society. Members' Lantern Night.

#### MONDAY, FEBRUARY 4.

South London Photographic Society. "Steps Toward Picture-Making by Photography." H. Snowden Ward, F.R.P.S.  
Lancaster Photographic Society. Federation Lantern Slides.  
Southampton Camera Club. Lantern Slide Competitions. 1. Landscape or Sea-Scene. 2. Flowers or Still Life.  
Oxford Camera Club. Annual General Meeting.  
Preston Camera Club. "The Carbon Process." Demonstrated. The Autotype Co.  
Leek Photographic Society. Monthly Lantern Night.  
Aldershot and District Photo. Society. "Latest Kodak Productions."  
Canterbury Camera Club. "Tabloid Brand Photographic Chemicals."  
Catford and Forest Hill Photographic Society. Print Competition. "Ozobrome." Demonstrated.  
Bowes Park Photographic Society. "Practical Hints in Pictorial Work." A. Horsley Hinton.  
Erdington Photographic Society. "Self-Toning Paper."  
Wilkesden Photographic Society. "Leading Principles in Velox Manipulation."  
Darwen Photo. Society. "Enlarged Negatives on 'Rotograph' Negative Paper."  
Attercliffe Photographic Society, Sheffield. "The Photographic Lens." C. P. Goerz.

#### TUESDAY, FEBRUARY 5.

Royal Photographic Society. The Second of a Series of Demonstrations upon Early Photographic Processes. "Talbot's Paper Process." Thomas Bolas, F.I.C., F.C.S.  
Stafford Photographic Society. "Elementary Photographic Chemistry." H. and F. Cliff.  
Darlington Camera Club. "A Holiday in Belgium." R. W. Chapman.  
Hove Camera Club. Open Night.  
Liverpool Amateur Photographic Association. Auction of Members' Superfluous Goods.  
Manchester Amateur Photographic Society. "Bromide Enlarging." J. D. Leigh.  
Blyth and District Camera Club. "Mounting Exhibition Prints." A. D. Miller.  
Hackney Photographic Society. Smoking Concert.  
Sheffield Photographic Society. Photography Competition Slides.  
Worthing Camera Club. "Wellington New S.C.P. Lantern Plates, S.C.P. Gaslight Papers, Bromide Printing and Toning." Demonstrated. A. H. Dunn, F.R.G.S., F.R.P.S.  
Otley and District Camera Club. "Postcard Photography on 'Rotograph' and 'Rotox' Postcards."  
Aldrincham Photographic Society. "Sports and Pastime with the Goerz-Anschutz Folding Camera."

Border City Camera Club, Carlisle. "Pictures with the Goerz Lens."  
Rotherham Photographic Society. Social Evening.

#### WEDNESDAY, FEBRUARY 6.

Borough Polytechnic Photographic Society. "Ozobrome." Mr. Manly.  
North Middlesex Photographic Society. Lantern Slide Competition.  
Everton Camera Club. "Finotype Process." Ernest Ives.  
Leicester and Leicestershire Photographic Society. Home-made Apparatus.  
Members. "Ozotype and Ozobrome." H. L. Hopkins and Harry Walker.  
Edinburgh Photographic Society. "Lawn Tennis Photography." A. Walla M'Gregor.  
Bristol Photographic Club. "Ozobrome." T. W. Brown.  
Leeds Camera Club. "Enlarged Negatives on 'Rotograph' Negative Paper." O. S. Dawson.

#### THURSDAY, FEBRUARY 7.

Blenheim Club. "The Women and Girls of Many Lands." Clive Holland.  
Richmond Camera Club. "Development and the Negative." T. A. Coysh.  
Hull Photographic Society. "Marine Photography." F. J. Mortimer, F.R.P.S., L.C.S.  
School of Photo-Engraving. "Photographic Printing in Natural Colours."  
North West London Photographic Society. "Our Chapter Houses." E. W. Harvey Pper.  
Tunbridge Wells Amateur Photographic Association. "Photography by Artificial Light." H. Wild.  
Rugby Photographic Society. "Ozobrome." Demonstrated.  
Chelsea and District Photographic Society. "Pictorial Composition." A. G. Mountford.  
Small Heath Photographic Society. "Enlarging Simplified."  
Halifax Camera Club. "Enlarging on 'Rotograph' Bromide Paper, including a Chat on Toning Bromide Paper."  
Handsworth Photographic Society. "The Production of Negatives with Various Developers."  
London and Provincial Photographic Association. Lantern Slide Making. "Dry Plate." J. S. Teape.

### ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held on Tuesday, January 29, Mr. Thomas Bolas, F.I.C., in the chair.

Mr. W. Beck exhibited and explained the "Cervex" shutter of Messrs. R. and J. Beck, Ltd.

Mr. Robert T. Haines read a paper on "Animated Photography and the Principles of Duplex Projection," in which he described a system of cinematographic projection, in which the positive image projected was never at any time obscured, even partially, and from which, therefore, flicker would be entirely absent. The system depended upon the alternation of the odd and even pictures in a film on a band almost double the width of the upon which the negatives were taken. These alternate pictures were projected, one by one lens and one by another, accurately paired with the first, and the mechanism of the instrument provided for one picture being cut off whilst the other was being brought into action. The lecturer described the first apparatus constructed by himself, in which two lights were used, but he found that it was impossible to maintain exact equality of the two illuminants, and therefore in a later instrument he had used a single arc, the light of which was deflected to the two projection systems by mirrors. The instrument was being constructed in Paris, but Mr. Haines could not say when it would be completed.

Mr. H. V. Hopwood referred to the present unsatisfactory conditions of cinematographic projection, whereby the films were run through at an immensely higher speed than that at which they were taken, with the result that a trotting horse gave the speed of a gallop without its action, and persons who were actually walking in a street assumed a gait which was nondescript. This was simply due to the efforts of the operators to counteract the flicker of the cinematograph by decreasing the dark intervals—at the expense, however, of a natural and pleasing reproduction. Mr. Hopwood referred to the curve of an impression on the retina, and thought that the removal of flicker from a cinematographic effect would be found to be connected with the curious curve representing the impression of any strong light upon the human retina.

Dr. T. C. Porter referred to two papers by himself on the cause of flicker in cinematograph work read before the Royal Society. In these papers he gave calculations whereby flicker might be entirely removed, and he thought that mechanicians and others interested in the cinematograph might find it of some advantage to refer to these communications.

Mr. R. R. Beard also mentioned some practical conditions tending to the extinction of flicker.

Dr. T. C. Porter then read a paper on "Some Extensions of Von Helmholtz's Work on Stereo-Photography." He commenced by explaining the principles of true stereoscopic effect, the cause of which, he maintained, was the effort which each eye had to make in order to bring its line of vision from parallelism to convergence upon a distant object. The angle through which the line of sight had to be brought was greater the nearer an object, and the effort necessary to cause convergence upon objects at different distances was the cause, he declared, of the true stereoscopic effect. He had found

by actual experiment that there was a limit, at no very great distance from the eye, to this true stereoscopic effect, but the limit was greatly removed if the distance between the two eyes could be artificially increased by optical means, such as were suggested many years ago by Von Helmholtz in the shape of a pair of mirrors which reflected and re-reflected the rays reaching the eye. By this artificial means it was possible to intensify the ocular stereoscopic powers, and the same principle might be extended to stereoscopic photography to practically any extent. Dr. Porter gave instances, and exhibited photographs in illustration thereof, of the means which was thus afforded of measuring the distance of natural objects such as a landscape, clouds, etc., and expressed the view that greater attention should be given to this application of stereoscopy for military and other purposes. Little time was left for discussion, and the meeting closed with the usual votes of thanks to the readers of the papers.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—At the meeting held on Thursday, January 24, Mr. Freshwater in the chair, the Chairman read a paper by Mr. Herbert E. Ives, upon "Improvements in the Diffraction Process of Colour-Photography." The Joly process was noted in some detail as having a direct bearing on the newer methods. To eliminate the grating effects of the narrow strips of gratings considered at lines, the device is used of making the strips (Joly lines) run at right angles to the diffraction grating lines, so that the spectra produced by them are thrown off in another direction, and do not enter the eye. The diffraction lines furnishing the three primary colours are:—2,400 to the inch for the red; 3,000 for the green, and 3,500 for the blue, and these are used in groups of three, of which there should be at least 200 groups to the inch. When viewed with the lens the pictures are entirely free from the defects of the old Joly system, the colours being both pure and brilliant, and the lines being too fine to be visible. The "Diffraction Chromoscope," Mr. Ives' invention for viewing the views, was shown by Mr. Freshwater, as were also slides the beauty of which were much admired by the members present. It was understood that the apparatus is shortly to be placed upon the market by Messrs. Newton and Co., and that further improvements might be expected, inasmuch as it was expected to be able to attach the apparatus to the ordinary lantern for projection, and also for making the pictures directly in the camera.

**CROYDON CAMERA CLUB.**—The annual meeting was held on the 3rd ult., and disclosed a very satisfactory state of affairs. Thanks to the untiring energy and business ability of its hon. secretary (Mr. H. M. Bennett), instead of an expected deficit due to the heavy expenses occasioned by the club's removal to its new premises, a good balance in hand was announced. Mr. A. E. Isaac was appointed president in place of Mr. W. H. Smith (resigned), and a hearty vote of thanks was deservedly accorded the latter. He, and the Council generally, are to be congratulated on having arranged a record fixture list in the past year.

**SOUTHAMPTON CAMERA CLUB.**—Mr. W. F. T. Wastell, on Monday last lectured on "A Dive into Belgium," and for over an hour entertained and interested a numerous audience.

Mr. GIDEON CLARK has been appointed secretary of the South London Photographic Society, and all communications should in future be addressed to him at 101, Calbourne Road, Balham, S.W.

The International Society of Painters.—Photographers are constantly being told that they should study works of art. We hope they take the good advice. They would learn a great number of lessons, if they were to visit the present exhibition now open at the New Gallery. The choicest thing, in our opinion, is Oliver Hall's "Sandpits," which is as good as an old chrome and very like one. Next, to learn what is meant by atmosphere, the photographer should study Emile Claus's "Matinée de Septembre," and George Buysse's "Morning in March." To portraitists we recommend Lavery's "The Hammock," a charming study in posing and illumination, and Wm. Nicholson's "The Paper Cap." The much boomed Rodin shows at last the long expected bust of Bernard Shaw. It would make a decent figure-head for a ship. The contour of the back of the head is not so good as that of any china doll. It is a bad likeness, and is entirely without grace or beauty.

## News and Notes.

**DEATH of a Consett Photographer.**—The death occurred shortly after ten o'clock on Wednesday, January 23, of Mr. Venice Dunn, photographer, of Medomsley Road, Consett, at the age of 55 years, after a protracted illness. For a few years Mr. Dunn represented Consett on the Lanchester Board of Guardians. The deceased built up an extensive business in the district as a photographer and dealer in artists' materials.

At the annual general meeting of the Bowes Park and District Photographic Society, on January 21, the following officers were elected for the ensuing year:—President, E. H. Down; Vice-Presidents, R. Core Gardner and W. T. P. Cunningham; Hon. Treasurer, H. Oliver; Hon. Librarian, F. C. Hornsey; Hon. Secretary, C. S. Carr; Council, J. A. Lovegrove, C. W. Peacock, and A. G. Warren. The annual exhibition will be held from February 21 to 23. Residents in the locality wishing to avail themselves of the privileges of membership should communicate with the Hon. Sec., Mr. C. S. Carr, 5, Earham Road, Bowes Park, N.

Mr. A. E. HARRIS, Hon. Sec. of the Cardiff Photographic Society, writes to say that, whilst their exhibition, which opens on February 15, is a members' show, in which there is no adjudication and no prizes are offered, they will be glad to receive, as on previous occasions, pictures from any outside workers, provided these are sent at the owner's risk and expense. Such exhibits should be addressed to the Society, at 7 and 8, Working Street, Cardiff.

MEMBERS of the Blenheim Club are to be congratulated upon the tempting programme of lectures provided for them during the current session, which will be held at the Club, 12, St. James's Square, S.W., on Thursday evenings at 8.30. Amongst these we note "The Women and Girls of many Lands," by Clive Holland; "An Architect's Tour on the Loire and in Poitou," by G. A. T. Midleton, A.R.I.B.A.; and "Picturesque India," by Mr. E. R. Ashton.

THE Lumière N.A. Company write: "We shall be glad if you will give publicity to the fact that the reports of a fire at our factory, which have recently appeared in the English press, owe their origin to a small outbreak occurring in a portion of the old factories. We have assurances from Messrs. Lumière that its effect is negligible, and that it has occasioned not the slightest delay or inconvenience in delivery of orders."

"LA FOTOGRAFIA ARTISTICA."—Our Turin contemporary of the above name is holding a great international competition for artistic and scientific photography, the interesting prospectus of which, in English, as written at Turin, reaches our table. We read that Messrs. J. H. Dallmeyer, Ltd., offer "a stegmatal objective, with obturateur 'Compound' of aluminium, and a tele-objective, 'Adon,'" and that "each concurrent will not have more than a prize for category. The works of the photographer of profession will be judged separately from those of the amateur."

**METRIC WEIGHTS.**—Two sets of tables of English and metric equivalents are sent to us by Mr. P. E. Radley, the compiler and publisher, of 30, Theobald's Road, London, W.C. The one is a 64-page booklet, and the other an eyeletted card for hanging. Both give a great variety of factors for conversion from one system to the other, though the requirements of photographers, we believe are better met by more detailed tables giving the equivalents of grains and ounces, and fluid ounces in grammes and cubic centimetres respectively.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—With the desire of helping the younger hands at photography, the members of the above association are arranging a series of special elementary lectures and demonstrations, each section being taken by the older members who have given special attention to the work in hand. Visitors are ever welcome at the meetings of this association at the White Swan Hotel, Tudor Street, E.C., on Thursdays, at 8 p.m.

We would remind intending exhibitors that entries for the exhibition of the Nottingham Camera Club close on Feb. 14. The awards in this exhibition will take the form of pictures to the value of one guinea to be purchased from the exhibition, instead of the usual plaques.

## Commercial & Legal Intelligence.

**SEASHORE Photography.**—At the Scarborough County Court, on January 24, his Honour Judge Dodd gave a judgment in the case of the Sherburn Rural District Council and George H. Doran, Filey, photographer, who claimed £1 10s. and an injunction. His Honour, in giving judgment, said that in this case the Sherburn Rural District Council brought an action to recover from Mr Doran, a photographer, who for some years had lived and carried on business at Filey, a sum of 30s., balance of £3 which it was alleged he agreed to pay the plaintiffs for the exclusive right to have a photographic cart on Muston Sands, to photograph persons or things upon the sands during the season of 1905, and also for an injunction to restrain the defendant from using the sands as a photographic stand without the consent of the plaintiffs. In the course of the case, upon the application of Mr. Perks, the counsel for the plaintiffs, he (his Honour) added a claim for damages for trespass upon the sands by the defendant in taking photographs upon the sands, and using the sands for the purpose of taking photographs thereon, without the consent of the plaintiffs. With regard to the original claim in the action, the claim founded upon the alleged agreement, the plaintiffs did not, in his judgment, succeed in proving that the defendant did agree to pay them the 30s. balance for the season of 1905. The plaintiffs must rest their case wholly upon the claim for damages for trespass in the year 1906, which was added, as his Honour had stated, to the original claim. With regard to the added claim, the Lord of the Manor, Mr. Mitford, was undoubtedly in possession, and had been so for many years, of the foreshore in question, and whilst in such possession let the sands to the present plaintiffs to hold, as his tenants, on certain terms. It was proved by very clear evidence that at all times material to that action the present plaintiffs were in possession as such tenants of the Muston Sands, and consequently were entitled to hold those sands as against any trespasser or person having no title. His Honour, therefore, found that the defendant was, in 1906, a trespasser, and liable in damages, which, under the circumstances, he assessed at a nominal sum of 5s. Should the defendant, or any other person, without right, wilfully persist in trespassing whilst the present plaintiffs were in possession of the sands, he had no doubt damages for such a trespass deliberately committed after the plaintiffs' rights had been made plain in that action, would be calculated upon a very different scale.

**A BUILDING Lawsuit.**—Lord Johnstone last week closed the record in an action by Charles Sweet, photographer, Rothsay, against W. C. Muir, draper, Montague Street, Rothsay, for £700 damages. Pursuer and defender are proprietors of adjoining subjects at 18 and 19, Battery Place, Rothsay, which formed one building. In 1905 defender took down the house at 18 and proceeded to erect a tenement of four storeys. During the construction of the tenement pursuer took out interdict against defender for encroachments on mutual property, but an agreement was come to under which defender undertook to do certain things which his operations had rendered necessary. Pursuer says defender has failed to implement the agreement. He further complains that defender's operations have caused sinking of the mutual wall and otherwise injury to his property, through which he has suffered damage and loss to the extent of the sum concluded for. Defender says the house he took down, as well as pursuer's, was over 70 years old. He states that the work has been carried out with due regard to the interests of the pursuer, and all unnecessary disturbance or injury to the neighbouring property has been, as far as possible, carefully avoided. He avers that he has observed the terms of the agreement, and, without prejudice, again offers to restore any damage caused by his operations, as same might be determined by a man of skill. He denies pursuer's averments of damage, and pleads that pursuer has no title to sue. The case was sent to the procedure roll.

**W. GRIGGS AND SONS (1906), LTD.,** Peckham, S.E.—Lien registered January 10, for £5,000 six per cent. debentures, part of £7,000 authorised; no trustees; secured on the undertaking, property, assets, and the uncalled capital, present and future, including the business of photo engravers and chromo-lithographers carried on in Peckham, S.E.

**SOUTHWARK Photo Engraving Company, Limited.**—Issue on 10th January of £1,500 6 per cent. debentures, being the whole of a series created same date, charged on the company's undertaking and property, present and future, including uncalled capital.

## Correspondence.

*\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*\* \* We do not undertake responsibility for the opinions expressed by our correspondents.*

### ADVERTISING.

To the Editors.

Gentlemen,—In a letter appearing in your issue of the 25th inst., Ilford, Limited, charge us with discourtesy towards themselves in the wording of an advertisement of Portrait Velox issued by us. May we be allowed to present the other side of the subject?

The name "Portrait" Velox was adopted by us over ten years ago to describe a particular texture and quality of gaslight paper. During the whole of that period it has been prominently advertised and a large public now know it and order it under that name. The exclusive use of this word by us has been respected until recently by all rival manufacturers—a striking testimony to the existence of those "soft manners," referred to by Ilford, Limited, in their letter, and which we, with them, are delighted to recognise.

Yet, without warning, Ilford, Limited (with some others), forgetting the gentle courtesy for which photographic manufacturers are famous, first of all copy, as nearly as they can, the precise texture and general appearance of our "Portrait Velox," and next proceed to appropriate the very name "Portrait" which we have used unchallenged for so long a time, and this is the more difficult to understand seeing that a host of other suitable names was at their disposal.

Hence the publication of our advertisement, which was not levelled at Ilford, Limited, for this imitation of name, as stated, is not confined solely to them. We felt that the circumstances compelled us to offer a caution to the public, who, we held, were more than likely to suffer confusion, as to which was the original "Portrait" paper and which the imitation.

We cannot agree with Ilford, Limited, in classing the word "Portrait" with such words as "Plates" and "Papers." These latter are common property, being descriptive of certain kinds of manufactured articles; the word "Portrait" is descriptive of certain kind of picture, and, as such, is common property; but it is in no sense descriptive of a certain kind of paper, except in so far as it has become so through our own special application of the word during a very long period.

Therefore, with your permission, we desire to return, if possible without wounding your correspondent's feelings, this cap of discourtesy, for, in our view, it does not fit us. —Yours truly,

JOHN J. GRIFFIN AND SONS, LTD.

### THE USE OF FLAMING SUNLIGHT ARCS IN PORTRAITURE.

To the Editors.

Gentlemen,—Will you allow me a little space on the above subject to add my mite, and also to elicit, if I can, a little information?

First of all, with regard to the cost of the flame arc, which, presume, is inclusive of, if not the same as, the "Excello." At the York meeting of the British Association last August, Professor Silvanus Thompson gave a lecture on "The Manufacture of Light," which I had the pleasure of hearing, and which has since been published in book form; a great deal of very valuable information was given, much, however, of little photographic value. The following items, however, extracted from a much more complete table, have direct bearing on the cost of the two arcs.

		Efficiency.				Cost.
	Spherical c.p.	Watts.	Watts per candle.	B.T.U. per c. hour.	Luminous Efficiency.	Pence per 1,000 candle-hour
Ordinary arc...	353	440	1.26	3.71	0.00318	2.40
Flame arc .....	1655	440	0.265	0.78	0.01080	0.504

B.T.U. of course means British Thermal Units.

The cost of the current is taken at 2.4d. per kilowatt hour or unit.

The above cost naturally refers to the luminous efficiency and not the photographic, but the figures are interesting if not exactly applicable, and there must be some ratio between

the two, for I take it that the addition of the flaming material could not appreciably reduce the photographic action. In fact, the flaming arc owes its colour principally to the introduction of a calcium salt, one would naturally suppose that the photographic action might be increased.

Some rough idea of this may be gained from the spectra reproduced in your issue for January 11, p. 21, but unfortunately these, I think, produced with a prismatic spectrograph, and there being no wave length or other scale, speculation would be but wild.

Mr. Payne says that there is more active red than yellow light in the yellow flame carbons. Is this correct? May it not happen that the red square of the Chapman Jones sensitometer transmits orange and yellow, as well as the red, and therefore there is a greater range of the spectrum to act than in the yellow? What I should like to know is the region of the spectrum transmitted by the coloured patches in the above sensitometer, and whether Mr. Payne considers it a reliable instrument for an approximate guide to the colour sensitiveness of a plate.

I beg to enclose a copy of Professor Thompson's book for your perusal, as there is much which might interest you or your readers. Yours faithfully, A. GASCOIGNE.

[We are grateful to our correspondent for his courtesy, and we hope to return to the subject of arc illumination generally, when one of the information given in Professor Thompson's book will be useful. "The Manufacture of Light," as Professor Thompson's book is titled, is published by Macmillan and Co., price 1s.—S. B.J.]

#### PHOTOGRAPHIC ASSISTANTS' PROTECTIVE SOCIETY.

To the Editors.

Gentlemen,—Up to the time of writing nine more persons have kindly sent in their names. This makes the total of 102 members. Since my last letter of January 4 several of my correspondents have been trying to persuade me to take a different course as regards the forming of a society. After lengthy consideration I have decided to do so. Before giving the only suggestion it is only fair that I should give my reason for doing so. A great many who have written to me are strongly of the opinion that we certainly ought to hamper the P.P.A. at present, as the good work they are doing is certainly on the increase. The general opinion is that we should leave the society open, so that when enough members have been enrolled, their decision could be taken as to what method of procedure the society should take. If the members are agreeable to join hands with the P.P.A. in any other good work they could do so. If this is the reason of a great many not joining the society we are trying to form, then I hope the change of leaving the society open will bring the desired result.

The following suggestion has been sent:—

That a meeting be called in London of assistants of all grades, managers, etc., to discuss the formation of a society. A committee be elected, and books opened for the admission of members. A declaration to be issued to all assistants, etc., applying for membership, giving the rules and objects of the society."

If I can get enough London assistants to arrange with me a special meeting I shall be willing to travel to London for the express purpose. Will all those assistants in London and district who are willing to meet me please inform me, and I will endeavour to make arrangements accordingly? This will now prove whether the assistants will rally to the cause of a society.

One point I wish to particularly mention is that several of my correspondents are very pleased with the managers' suggestion of January 4, and they are now firmly of the opinion that the P.P.A. can open out some scheme whereby they can become members. If the P.P.A. does so, then I sincerely hope a good number will rally to the cause.—Yours faithfully, U. DOUSE.

Richmond Terrace, Romsey, Hants.

**SULPHITE OF SODA.**—The Lumière N. A. Co., ask to be allowed to correct the information sent for publication last week. The sulphite of soda is sold in bottles containing 17 ozs. at 8d., and 35 ozs. at 1s. 3d., not 10 ozs. for 8d. as previously announced.

## Answers to Correspondents.

- \* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \* \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

#### PHOTOGRAPHS REGISTERED:—

- H. U. Schofield, 5, Aspect Terrace, Pudsey, near Leeds. Photograph of a Group of Three Clergymen.
- E. Gael, 12, Leopold Road, Bristol, N. Photograph (Combination) of Horfield Barracks.
- F. Ormiston-Smith, Grindelwald, Bernese Oberland, Switzerland. Photograph entitled "Winter Sunshine".
- Isaac Slater, Mostyn Street, Llandudno. Photograph of Roman Coins found in Little Orme's Head, Llandudno.
- T. Taylor, 33, St. Albans, Liverpool. Photograph of the Accrington Stanley Association Football Team. Season 1906-7.
- J. Boak, 39, Newport Road, Middlesbrough. Photograph of the Boat "Annie," and Three Boatmen, with Skandael ss. "Awa Maru."
- A. Ridley, Tenterden, Ashford, Kent. Five Photographs of Interiors of Miss Ellen Terry's Farm at Smalhythe, Tenterden.
- J. W. Briggs, 13, Station Street, Kirby-in-Ashfield, Notts. Photograph of Organ and Pulpit Destroyed by Fire in St. Wilfred's Church, Kirby.
- E. Bailey, 13, Castle Street, Canterbury. Photograph of Opening of the Rifle Range at Canterbury by the Mayor.
- L. M. P.—"The Ilford Manual of Photography," 1s., should be as useful to you as any other.

**STEREOSCOPES.**—I should be glad if you will mention the name and address of makers of the "one-eyed stereoscope."—J. A.

Mr. Theodore Brown, 26, Drummond Road, Bournemouth, has one, if not more, patterns of such instruments. One picture is viewed by one eye through the apparatus, while the second picture is viewed direct by the other eye.

**GLAZING POSTCARDS.**—Will you kindly inform me in your columns where I can obtain liquid gelatine for glazing picture postcards?—T. H. W.

It is not sold. The prints are glazed with a hot solution of ordinary gelatine by firms such as McCaw, Stevenson, and Orr, Sloe Lane, E.C., and Strane and Co., Belfast, who do such work for the trade.

**AMERICAN PHOTOGRAPHS.**—I shall be glad to know if the American portraits now being exhibited at your offices are likely to be shown in the North of England in the near future. I am anxious to see the exhibition, but await your reply before finally deciding to come up to London.—A. O. FISHER.

The prints will be returned to Herr Dührkoop, in Hamburg, at the close of the exhibition here.

**REMOVING RETOUCHING.**—I have a negative which I was foolish enough to print from without varnishing, with the consequence that I now have silver stains on it. As it is retouched, I would be glad to have an answer to the following through the medium of your valuable paper. Will you kindly say how to remove retouching medium from negative so that I can remove silver stains?—BERRY.

Rub the surface with cotton wool soaked in methylated spirit or turpentine.

**PHOTO-BUTTONS.**—Can you oblige me with the names and addresses of makers of "photo-buttons"? We have searched the ALMANAC and BRITISH JOURNAL, but are unable to find anyone advertising in that line.—BRISON AND CO.

Fallowfield, page 1265 of ALMANAC, is the source of supply. The articles are not made in this country.

**BLEACH-OUT PROCESS.**—On page 648 of the ALMANAC, 1907, you give an outline of the "bleach-out" process, with Dr. Neuhaus's formula for the coating mixture. 1. I do not know whether it is intended that methylene blue solution should be decimal one in fifty or one in fifty. Auramine solution, I suppose, is decimal one in fifty. Will you kindly explain what was intended? 2. Will you also say where primrose, Victorian blue,

curcumine, and anaethol may be obtained? 3. Also, where celluloid in quarter-plate size can be obtained?—G. B.

1. Decimal one. 2. The Bayer Co., Mosley Street, Manchester, or Mawson and Swan, Newcastle-on-Tyne. 3. In small quantities from Fallowfield or Houghton; in bulk from Guiterman and Co., 35 and 36, Aldermanbury E.C.

G. F. H. The idea seems a good one, so far as we can judge from the photographs, but we doubt if the sale will justify a patent. We may tell you that to take out and uphold a patent costs in all £100. We doubt if the sale of your device would stand this. You might take out a provisional protection, which will cost you only a guinea.

TRADE NAMES.—I am bringing out a new series of picture postcards, which I wish to call the "—" series. Can you tell me how I can find out if this name has already been used; and if not, what would be the cost of registering it, and how would be the proper way to do it?—AREMAC.

You can see from a file of the "Trade Marks Journal," which is probably in your free library. Otherwise we can only suggest your addressing your query to a stationery journal, such as the "Stationery Trades Journal," 12, Warwick Lane, E.C., or employing a firm to search the files at the Patent Office. We have never seen the name on postcards. You can obtain instructions for registration from the Patent Office.

REV. T. W. L.—The f/4.5 Holostigmat as recently reviewed in these columns. The single components can be used and are obtainable, each of double the focal length of the complete lens, or of unequal foci. We know of no camera of the same type which can be used at double extension except by means of a separate attachment. We suggest a folding camera of the hand-stand (hinged baseboard) type, a number of which you will see described in the ALMANAC.

SITUATION IN CAIRO.—Will you kindly tell me, through the medium of your valuable paper, if there is any chance of a young man obtaining a situation in Egypt—for preference, Cairo; and where, or in what paper, could he obtain same?—EGYPT.

We cannot say. You might insert an advertisement in "Le Journal" or "Sphinx," the former a French and the latter an English newspaper in Cairo.

EMULSION MAKING.—I shall be much obliged if you will refer me to the best and latest information published on the subject of making bromide emulsions for plates and paper.—HAROLD WEBB.

The best and latest information is given in Eder's "Handbuch der Photographie," Vol. III., but this is in German, and no English translation has yet appeared. The last English work was Abney's "Photography with Emulsions," published by Sampson Low, and Co., which, we believe, is out of print.

PRINTING THROUGH GREEN GLASS.—Can you tell me why printing through blue, signal-green, or yellow glass so greatly alters the character of a print in platinum or in certain brands of P.O.P.? TOXO.

In the case of platinum printing, the variation in character is entirely due to the fact that the coloured glass weakens the light, and therefore more brilliant prints are obtained. Precisely the same results may be obtained by covering the negative with matt varnish or tissue paper. This is assuming that the colour of the negative image is black; if there is any stain in the image then the action of the glass may intensify this: thus yellowish negatives print more brilliantly through blue or blue-green glass, whilst bluish negatives will print better through yellow glass. In the case of P.O.P., the action of the coloured glass is dependent on the alteration of the spectrum composition of the light. Chloride of silver is sensitive from G in the idigo to the ultra-violet with the maximum at H. Most of the organic salts of silver are sensitive not only to this region, but also from G to beyond D in the yellow. If we use then a coloured glass which absorbs the violet and ultra-violet, so as to confine the printing action to the green and yellow light, the organic salt of silver will be more acted upon than the chloride, and, as a rule, a shorter scale of gradation is obtained—that is, the prints are harder.

JAMES STEWART.—Most of the coal-tar colours are transparent, and the majority of them are soluble in alcohol. With such you have only to add some of the colour to the depth desired to negative varnish, and apply to plain glass as you would

varnish a negative. You do not mention the tints you require, or we would suggest those you should get that are soluble in alcohol. However, when you order the dyes, specify those soluble in spirit.

A. J. R.—1. Yes. 2. We know nothing of Mr. F. 3. We cannot say positively, but we believe from Mattos, Limited, 36, Arundel Square, London, N.

F. SANDERSON.—It is not possible for us to say. The dispute should be referred to your solicitor.

CANINE PHOTOGRAPHY.—I should be pleased if you could inform me how I might photograph an Airedale dog, about twelve months old—a dog that has all good points for showing, but will not stand. Is there any way to wire him, or would you suggest any special plates or lens for this?—GRIP.

None that we are acquainted with. Your problem would be more appropriately addressed to a journal such as the "Field," Chancery Lane, W.C.

ARTIFICIAL NEGATIVES.—In your issue of January 18 is an instructive article, extracted from Liesegang's "Photographisches Almanach," on "Artificial Negatives," giving two formulae for the "ground" with which to coat a plate preparatory to etching it. In each case the instructions are to coat a plate and let it dry; but as a further preparation we are told in the one process to dust the plate with graphite, and in the other to rub it over with a mixture of lampblack and mucilage. The reason for this is not given, and as it is not obvious in either case what part this final step plays in the preparation of the plate—for the essential conditions seem to have been fulfilled when once the plate is grounded and dried—I shall be obliged if you can say whether this is essential, and, if so, why?—DONALD GUNN.

The purpose of these coatings is presumably to enable the operator to see the lines which are traced in from a print or drawing. If the drawing can be done direct on to the plate there is no need for this.

F. J. ROBINSON.—The book has scarcely the value of the published price, owing to the number of editions through which it passed. Nor is the other of any historical value.

BOOKS ON RETOUCHING.—Might I trouble you to tell me the name, price, and publishers of a good reliable book on retouching?—PORTRAITURE.

"Retouching," by Arthur Whiting (Dawbarn and Ward, ls.), and "Practical Retouching," by Drinkwater Butt (Iliffe and Sons, Limited, ls.).

L. NEGUS.—Nothing of the kind on the English market.

AMERICAN JOURNALS.—I take the liberty to ask you if you would give me information as to where I could obtain some American journals and papers of photography?—V. G. A.

See the list of foreign publications on pp. 855 to 858 of the ALMANAC. Messrs. Dawbarn and Ward, Farringdon Avenue, will get any of them for you.

G. K. BEVANE (Highgate).—An excellent formula is the first one on page 994 of the ALMANAC.

A. DYE.—1. Try Sanders and Crowhurst, Shaftesbury Avenue, London, W. They are as likely as any one. 2. Usually the corrections for spherical aberration, coma, etc., are better.

W. KEAST.—We know of none, except O. Sichel and Co., 52, Bunhill Row, London, E.C.

\*\*\* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

"The Right To One's Face." Miss Millar (Mrs. Lionel Monck), the well-known Gaiety actress, in the King's Bench Division last week, obtained an adverse verdict in an action brought to recover damages from a postcard publisher who issued portraits representing her in certain alleged objectionable costumes which had not actually assumed. (Pp. 94 and 108.)

A case in which the London and North-Western Railway Company claimed exemption under the Carriers Act for the loss of photographic enlargements was heard recently at Manchester. The company pleaded the clause in the Act respecting "pictures or paintings," but the judge held that the photographs were neither, in the meaning of the Act. (P. 94 and 108.)

A special report (by the representative of the BRITISH JOURNAL OF PHOTOGRAPHY) of Dr. Korn's demonstration of his telegraphic transmission of photographic images in Paris on Friday last appears on p. 103.

Part IV. of the notes on working-up with the aerograph deals with final points in the treatment of portraits. (P. 95.)

Filters for the photo-micrography of the common microscopic organisms have been worked out by Dr. C. E. K. Mees. (P. 100.)

A German paper journal gives tests for paper intended for the making of photographic materials. (P. 98.)

Formule for the Kallitype process by a well-known American worker of the process are given on p. 96.

Contents of the week include still another development-camera improvement in the Levy acid-blast etching machine for half-tones and a process of transferring resists to curved metal plates. (Pp. 104 and 105.)

The annual meeting of the Royal Photographic Society takes place on Tuesday next. Some items from the Council's report are given on p. 103.

C. Welborne Piper, in a recent communication to the Royal Photographic Society, describes his models of lens' aberrations to which recently a medal was awarded. (P. 102.)

## EX CATHEDRA.

### The Presidency of the R.P.S.

There is one most satisfactory announcement in the somewhat unsatisfactory literature which the Royal Photographic Society has issued to its members, and that is the unopposed nomination of Mr. J. C. S. Mummery to the presidency. Everyone who knows Mr. Mummery personally will applaud this choice, and to those at a distance it may be said that no one better qualified to discharge the duties of the office with grace and tact could have been selected to succeed Major-General Waterhouse, who, for the same reasons among others, has been a most popular president. But apart from personal qualifications, Mr. Mummery's position as a leading exponent of pictorial photography has earned for him, it may be said, the regard of all classes in that world of factions, though the fact is of even less importance to the Society than the record of the help, advice, and personal labour which the President to be has ungrudgingly given in all departments of the Society's life.

\* \* \*

### Photogravure for the Professional.

We have not infrequently commented on the neglect of that most beautiful of photo-mechanical processes, photogravure, as a medium for the multiplication of portraits taken in the way of business. Though scarcely any use is made of the process in these islands—Mr. Craig Annan is the only photographer who comes into mind as we write—we shall not be surprised to hear in the future of photogravures figuring with greater frequency in the price-lists of the leading photographers in a district. It is not likely that any number will undertake the preparation, and printing of the plates themselves, but the impressions may, nevertheless be obtained from one of the not very numerous houses doing good work in the process. Herr Dührkoop, of Hamburg, as we mentioned at the time of the exhibition of his portraiture at our offices, has made photogravure a feature of his studios, and we now see in the German papers that he offers to supply impressions from photographers' negatives under his own supervision. It is conceivable that a photographer in this country, with a mastery of the process, might similarly cultivate an outside business as a result of himself specialising in photogravure portraits.

\* \* \*

### Free sittings and the Postcard Case.

The recent decision as to Miss Gertie Millar's rights, or rather the absence of rights, in the reproductions of her photograph has evidently awakened many professional and other public persons to a lively sense of their position. They see clearly how they have played into the hand of the photographers who have offered them "free

sittings" and have thereby acquired absolute rights in the reproduction of the sitters' portraits unless such use can be proved to be defamatory. Thus we read in Monday's "Times" the angry letter of a "professional musician" complaining of the appearance of photographs of himself of all degrees of quality, and of the annoyance and trouble to which he is subjected by persons who beg the addition of his autograph to representations of himself which may at times be more truly described as caricatures. The fault here is evidently to be laid at the door of the half-tone engraver or "process" operator, not at that of the photographer, yet it does not seem to occur to the complainants that there is a very simple remedy for their grievances, viz., the payment of the photographer and the reservation to themselves of the copyright in the portraits. To talk about "exploitation of our personalities" and to describe the fruits of the compact with the photographer as "detestable traffic" is pure nonsense, but, at the same time, the occasion which is thus given to the use of such expressions is still another argument against the "free sitting" business, and still another reason for photographers to desert a system which lowers the dignity and strength of their profession, or makes these qualities more difficult to attain.

\* \* \*

**A Suggestion** The demonstration given at the Royal from Calotype. Photographic Society by Mr. Bolas on Tuesday is a reminder of the modern application of the ancient fixing process which Fox Talbot used. Talbot got rid of the excess of silver in his paper by treatment with sodium chloride and iodide, and by so doing removed the liability of the paper to darken further. Precisely the same principle can be usefully applied to P.O.P. in making prints intended to serve a purely temporary purpose. By printing out only to the depth required and treating for five minutes in a ten per cent. solution of common salt a print is obtained which will answer all ordinary exposure to light for a day or two. Equally may it be used in making enlarged negatives by direct enlargement in the camera, by which method a comparatively weak light can be used. The print thus treated will not stand exposure to a very strong illuminant, the electric arc at close quarters, for example.

#### Photographs and the Carriers Act.

The case in a Northern county court which is reported in our "Commercial and Legal" column this week possesses an interest other than that supplied by the admission of the Judge that, within the meaning of the Carriers Act, photographs are not pictures. The North Western Railway had taken the view that photographs might be described as "pictures or paintings," but their contention, it is due to them to state, was not put forward as an expression of their championing of photography for a place among the *beaux arts*, but purely on account of the clause in the Carriers Act which allowed them to require a declaration as to the consignment and payment at a higher rate. His Honour, however, could not class the photographs as "pictures" under the Act, a reflection upon the productions which is no doubt robbed of much of its bitterness to the firm of photographers by their recovery of damages from the railway company to the amount of £10 10s. and costs.

**DEATHS of Photographers.**—We have to announce the death of Mr. W. T. Holme, of Wellingborough, and of Mr. Herbert Wraggs, of Wigan, both professional photographers of standing in their respective forms. Also of Mr. J. Pemberton, photographic chemist, of Herne Bay, and a clever photographer, whose work appeared in the illustrated press.

#### THE "FAKED PHOTOGRAPHS" CASE.

MISS GERTIE MILLAR, of the Gaiety Theatre, will assuredly have the sympathy of all broad-minded people, as she has ours and that of her professional friends, in the verdict which was last week given against her in the action against a firm of postcard publishers. The action, which led to the action and the report of the proceedings in the courts appear on another page, but, expressed in half-a-dozen words, the dispute was as follows:—The publishers issued three postcards, in each of which the face was Miss Millar's but the body that of another person, real or imaginary. The body in one instance was actually in a nightdress, in another was represented emerging from an egg, and in a third was that of the picture, "La Source," where the figure's attire is the scantiest. These representations would lead the public to think that the lady whose face appeared on the card had actually posed for the portrait, and the action was brought for defamation of character on these grounds. The summing-up of the judge, endorsed by the jury in their verdict, was that there was no defamation, inasmuch as the actress had been photographed in various fancy costumes and photographs had been published with her approval. The learned judge drew a distinction between a representation of the actress in a theatrical part and one of her in non-theatrical part.

The case is one which needs to be brought before the public for the reason that it may lead to the erroneous belief that a photographer's licence in portraying public or private persons is very much greater than it is. The judge's summing-up appears to have ignored the existence of Miss Millar as a private individual, with rights equal with other ladies. According to him, a lady who performs on the stage in fancy costume is not entitled to the same remedy which, as the summing-up recognised, would be granted to a vicar's wife. Yet the actress, of all women, is exposed to comment reflecting on her character, and it is therefore all the more in need of the power to prevent the publication of any portraits which in any way reflect unfavourably upon her. The verdict would be explicit if it came from twelve elders of a century-old Puritanism, in whose eyes the respectability and character of a lady of the stage were non-existent qualities, but from a jury of Londoners, in these times when the private life of the theatrical favourites is almost as well known as every man's is to himself, should indulge such a conception, is not in the least credible. There is, indeed, explanation forthcoming, except the suggestion in the morning paper that the decision is merely an instance of the rigid administration of the sound law by some utterly lacking in taste.

While we join our protests to those of the defendant in the case and to the chorus of indignation from the green-rooms of all the theatres where such a picture postcard are to be found, from the lady who was Miss Camille Clifford downwards, our chief intention is to caution professional photographers as to the rights which they may make of portraits of which they have the copyright. In contradistinction from this case, which we have alluded to, and in which, according to the view, the rights of the private individual have been ignored, there are others in which the libellous or defamatory use of a photograph has been made the subject of a successful action. In an article which we published last week from an American source some instances were given of how the reproduction of a person's face has been checked in the United States, and similar instances may be cited in this country—for example, one of about a couple of years ago, in which Miss Marie Studholme prevented a dentist from using her photograph, with the teeth blocked out, as an advertisement of the art.

teeth supplied by him. These actions are not brought under copyright law, which has nothing to do with them, but under common law, by which photographers or publishers may be restrained from issuing copies of a person's photograph of such a nature as bring him into ridicule or to prejudice his commercial, social, or official position in the eyes of the public. We are not infrequently asked to advise our readers on this matter, and we are sometimes surprised at the eagerness shown by some photographers in small places to publish a picture postcard which they know is certain to offend a customer of theirs, even if it is not actually libellous or defamatory. On the other hand, the squeamishness of individuals is equally surprising, if we believe the cases which are brought to our notice, such as one in which a gentleman sought to remove a postcard photograph of a sea beach from circulation on account of the inclusion of the microscopic representation of himself in the distance in regulation bathing costume. The fact remains, however, that the rights of the private individual must be respected, and this position is not altered by the recent decision, in

the course of which, indeed, it has been re-affirmed. We are glad to see in the London papers the statements of a number of photographers discountenancing the method of the "faked photograph," and drawing attention to the courtesies which it is their custom to observe in the case of all photographs of which they hold the copyrights. As one or two firms point out, it is only by being very particular in the use which they allow to be made of such photographs that they could expect to retain their sitters' patronage.

One side issue from the case may be mentioned before we dismiss it from consideration. It concerns the postcard publishers, and is the speculation on the part of a barrister in the "Daily Express," that as the photographs purporting to represent the face and figure of Miss Millar were only in a partial sense representations of her, the public have a claim against the publishers or the latter against a producer who, contrary to contract, should supply such a faked portrait instead of a genuine one. We would rather not discuss the debatable points which such a proposition suggests.

## WORKING - UP AND COLOURING WITH THE AEROGRAPH.

[In this fourth instalment of a series of articles on the practical use of the air-brush in portrait work, some final points in monochrome work are considered. The concluding article, in next week's B.J., will deal with colouring.]

### Vignettes.

A few points in regard to making a perfect vignette would perhaps be useful. In this work the "aerograph" is extremely useful, and any worker with an "aerograph" should not be pardoned for putting into his pictures the old definition which was called vignetting in the early days of photographic finishing; the point to remember in doing a vignette is that your shadows gradually run out at all points, and that your lights run out less gradually—that is, after carrying your shadow down with the "aerograph," making them gradually disappear at a uniform rate, you may add the lights with the eraser, carrying your lights farther into your vignetting than you carry your shadows; but, of course, lights and shadows both disappear on arriving at the white paper. Generally speaking, the more gradual the vignetting is, the more pleasing the result. You may begin to vignette in a bust picture almost from the neck if it is done sufficiently gradually.

### A Hint as to Roundness.

Keep the outlines of your figures soft: the camera sees with only one eye, but people look at objects with two eyes, and every rounded object presents two outlines to the spectator. You cannot make two outlines in the portrait, but you can give a diffused outline, which will go a long way to convey the impression that your picture has substance to it. I have represented two balls (Fig. 4), which, if the process engraver and printer do justice to them, will show this point. A will look like a hemisphere rounded on the face but flat on the back, while B will look like a complete sphere, round on the back. They are shaded practically the same, the difference is in the outline.

### Backgrounds.

A great deal now remains to be said about backgrounds; it is a very important part of the picture. In fact, an artist who can secure fairly good prints, spot them, and put in skilful backgrounds, will receive more credit for his work than one who finishes the faces nicely and neglects the background. A good enlargement which is simply spotted and a skilfully executed

background added, to suit the head, will make an acceptable picture.

The first thing to be considered in a background is that it should carry out the composition of the picture. In the usual bust portrait the composition is pyramidal, and this determines the position of the colour which you are to place around the head. The next point which may be considered is to bring the interest, or, shall we say, the contrasts of light and shadow into the centre of the picture. To do this, if you were treating a bust portrait, say, of a man with a black coat, you would find

Fig. 4.

it desirable to add sufficient colour to the background above his shoulders to subdue the contrast which the black coat makes against the background. You must, therefore, make the shadow dark around the shoulders in such a portrait, and gradually disappearing to a point above the head.

### Atmosphere in Backgrounds.

Another thing to be remembered is to keep the general tone of your background at a point which will relieve the high

lights and lighter tints of the face by contrast, without destroying the strength of the shadows. Still another thing which is generally considered desirable is to add to the relief of the head by contrasting slightly light against dark, and dark against light, in the background. A better effect of relief is produced if you leave a slight halo about the head; it must not be sufficient to be noticeable. Now we have, so to speak, mentioned the broad lines of the background. You want one thing more, if it can be obtained, and that is the atmospheric effect, or effect of perspective around the head.

In the older school of photographic finishing this was accomplished by hatching. Coarse lines were hatched near the shoulder, gradually going away fainter in the distance. Hatching was also done to soften by contrast the finishing in the face. You can hatch these lines in with an "aerograph," if so desired, by thinning your colour very thin and setting your "aerograph" for a definite line by the little knurled band, and drawing the strokes at the proper angles with the point of the instrument close to the paper. Personally, however, we do not like the hatched backgrounds; they do not suggest to us anything in nature, and we are of the opinion that the atmospheric effect, or effect of perspective, can be better obtained by planes of shadows. To obtain a satisfactory cloud background it is not sufficient to make, what we may call, "lumpy" clouds: they must be clouds with perfectly defined edges, not hard, and with the least possible amount of contrast—but always planes of light and shadow to secure the atmospheric effect. And one must remember that the detail of this kind, which is put into the background, must be more marked at the lower part of the picture, near the shoulders, and gradually die away to an even

tint at the upper portion of the background. Torn blotting paper may be used as masks, and is employed by some artists to assist in producing this effect, but great care must be used not to make it look mechanical. The blotting paper must be torn in the right way and a little erasing done to take away its hard edge, and the colour when applied to be very thin so that the marking is scarcely perceptible. Having finished the shading of the background, the correcting and erasing of the lights of the picture complete the work.

You will not be able to leave extreme high lights on the forehead, nose, or eyes while shading the pictures; these must be erased, or scraped out, for the reason that these high lights for the most part have a sharp definition to them: the definition, of course, not to be abrupt—almost imperceptible—but it must still be sharp.

You will need to go over your work carefully to see that you have secured the likeness. Study the expression of the guide print, and, if you find your enlargement is different in any point, study it carefully until you have discovered which shadows produce the result, and correct them.

In correcting the picture a good practice is to study your guide print, and correct the shadows in your enlargement. See that they are as nearly right as possible. Then study the guide print from the point of view of the high lights, beginning with the extreme lights, and see that the high lights and lighter portions have the same degree of illumination. In this way you secure greater accuracy, and in a way prove your first corrections.

We must defer the chapter on colouring portraits until a later issue.

## THE KALLITYPE PROCESS.

(From the "Photo-Era.")

Kallitype as a method of photographic sun-printing may be said to have passed the experimental or doubtful stage. It is the method par excellence for the worker of serious purpose to whom the "fatal facility" of the gaslight paper has no appeal. Many there are among amateurs who sigh for results removed from the common. By printing on media of their own sensitising—paper of quality and texture that is rare—these fastidious ones may fulfil their desires.

As at first worked, kallitype had a most serious defect in the rustiness of the deeper shadows following the use of a negative of more than usual contrast. This trouble, however, has been eliminated, and the process is now capable of results quite the equal of platinotype, to which it is akin, the basis of both being ferric oxalate. We find in each the same richness in deposit of metallic particles, the same softness and beauty of gradation in half-tone, and the presence of those qualities that make the pictorial image more like a wash-drawing than a photograph.

The modifications of the original formulæ have been many, and for the greater part good, though some are rather involved as regards manipulation. For this reason I early sought for a more direct means than was then available for the production of prints in pure black and white, and I think I have succeeded. My process at least has the merit of cheapness, for the cost is trifling, in fact not much in excess of the "blue print." In brief, the process is as follows, and, as can be seen, is extremely simple.

A good paper is coated with the sensitiser, dried by artificial heat of low temperature, and is then printed under a negative.

There is a faint image, much as in a platinotype, but of a tawny hue. This image is instantly brought to full vigour in a bath of weak silver nitrate acidified with citric and oxalic acids. After about a minute the print is washed free of sediment, and is fixed for five minutes in weak hypo, after which it is washed for half an hour and dried on clean papers or between blotters.

The image is black, but many warm colours, from purple all through the red chalks to sepia, are quickly and easily obtainable by toning with uranium and fine cyanide of potassium, some of the colours and effects being rare and indeed very beautiful.

In regard to quality of paper, it should always be of linen, preference of course being accorded that specially made for photographic purposes. Excellent results, however, may be obtained on heavy bond and ledger stocks, Scotch linen ledger being among the best. This last comes in sheets, the dimensions of which are 19 x 24. This cuts to good advantage, whatever the size of plate employed. Nor are the common, everyday notepapers to be despised, where small sizes are demanded. Vellum, parchment, Irish linen, Berkshire mills, cream laid, may be here suggested. For soft effects, the more fibrous papers are in order, and these, as well as the Japan tissues, should have a generous portion of a good size, either of arrowroot or gelatine. Rub up in a bowl in a little cold water twenty grains of the arrowroot. Then pour on it, constantly stirring to prevent lumps, ten ounces of hot water. Bring to a boil, when the milkiness at first present will disappear. A couple of ounces of wood alcohol may be added once the mess is filtered.

For black-and-white effects the following has been found satisfactory:—

## Formula A.

Distilled water .....	1 oz.
Citrate of iron and ammonia .....	32 grs.
Ferric oxalate .....	16 grs.
Oxalate of potass .....	33 grs.
Oxalic acid .....	10 grs.
Chloride of copper .....	4 grs.
Citric acid .....	4 grs.
Silver nitrate .....	10 grs.
Gum arabic .....	10 grs.
Bichromate of potass., 5 per cent. sol.	10 drops.

For coating small sheets, 4 x 6 or 5 x 7, a wad of absorbent cotton will answer when but a few are wanted at a time; also where but a small portion is intended for printing and the effect of a careless wash-drawing is sought. For large sheets, however, a good camel's-hair brush is advisable, the flat variety, two or three inches wide, and rubber bound. It is a good plan to coat paper on a thick sheet of glass, holding the paper by four small metal clips, such as are used to hold neckties in place. A piece of the dimensions of 8½ x 11 in. will answer for most purposes. The size of paper will allow for two 5 x 7 or four 4 x 5 prints at each coating.

Pour a small quantity of the sensitiser on the upper section of the sheet, and with rapid strokes of the brush go over every part. The idea is to complete the coating of all parts before any one part has dried, thus insuring an even coating. With rough paper it is a good plan to first sponge with clear water, and when nearly dry, to apply the sensitiser, which insures the latter flowing into the meshes, a thing sometimes difficult to effect when the paper is bone dry.

Formula A may print rather slowly, but the blacks obtained are good. It is best adapted for use with rather hard, smooth papers, and for porous stock may require dilution. The generality of workers, I find are inclined to strong effects—good contrast—and lovers of low tones may find this sensitiser rather strong for their purposes. In such cases withhold from five to seven grains of the iron citrate to the ounce of solution. In preserving all details in the shadows it is best to use a rather weak sensitiser and give a double coating. Should the solution be found too weak, it may easily be made stronger by the addition of the iron salts.

Ferric oxalate being a somewhat difficult chemical to obtain outside of the large cities, I have made many attempts at a formula giving black tones.

## Formula B.

Distilled water .....	1 oz.
Citrate of iron and ammonia .....	50 grs.
Ferric oxalate .....	13 grs.
Oxalate of potass. ....	35 grs.
Chloride of copper .....	8 grs.
Oxalic acid .....	16 grs.
Silver nitrate .....	16 grs.
Gum arabic .....	10 grs.
Bichromate sol., 5 per cent. ....	5 to 10 drops for contrast.

For more contrast add one or more grains of the ferric oxalate. For contrasty negatives use a smooth paper, giving but one coat of sensitiser. For flat, overtimed negatives, use a rough paper and coat twice.

Printing should be effected in the sun. Print until the deeper shadows are well defined, the half-tones being invisible. In a snow scene, for example, or in the case of a white dress, in a portrait or figure study, no trace of the finer details should show.

The developer stock solution is:—

Distilled water .....	1 oz.
Citric acid .....	10 grs.
Silver nitrate .....	40 grs.
Phosphate of soda .....	1½ grs.

To seven drachms of water take one drachm of the stock solution and about a drachm of oxalic acid. A piece of the latter about an eighth of an inch in size will be near enough. For developing use a porcelain or glass tray, which should be kept clean and occasionally washed with muriatic acid.

Immerse prints face down, immediately turning them over to see that there are no bubbles present, which would leave white spots in the finished print. If there should happen to be any, break with a slight touch with the point of the finger. Development will be fully completed in a minute or less, nor can we overdo it once exposure is correct. Wash prints for a minute or so; then transfer to the clearing or fixing bath made up in the proportion of about two grains of hypo to the ounce of water. While for smooth papers five minutes will be sufficient for fixing, ten minutes may be safely accorded heavy, rough papers. Dingy whites indicate insufficient fixing and fading of the shadows when it is overdone, though there is not much danger of that unless drying has been too hasty. Complete operations by the usual wash for, say, half an hour.

For the sensitiser as well as the developer a dark bottle should be chosen. Add chemicals in the order specified, after which, without any shaking more than turning bottle upside down once or twice, put away for twenty-four hours in a dark place. At the end of this period stir up sediment from the bottom, shake well, and filter through absorbent cotton. The sole necessity for filtering is to free the solution from certain gritty particles which, if remaining, will mar the surface of fine papers in coating. Place a wad of cotton in the glass funnel, pour into the centre of this the solution, sediment and all, and gathering up the wad between fingers and thumb, squeeze all liquid back into the bottle. The gritty substances will remain in the meshes of the cotton.

To provide against possible failure, I herewith submit additional formulæ. For flat negatives, full of detail and overtimed, the following should give good results, and if it works out as it should the tone will be black, with a greenish cast:—

## Formula C.

Distilled water .....	1 oz.
Citrate of iron and ammonia .....	28 grs.
Ferric oxalate .....	23 grs.
Oxalate of potass. ....	35 grs.
Chloride of copper .....	8 grs.
Oxalic acid .....	15 grs.
Silver nitrate .....	19 grs.
Gum arabic .....	10 grs.
Bichromate sol., 5 per cent. ....	5 drops.

In all formulæ submitted there is a very careful balance of certain chemicals. For example, in this last a trifle less (a grain) of the silver will make a marked difference in the tone of the black. A slight excess of silver tends to green, while the same excess of copper makes for blue. Overmuch of the former means rusty shadows, while too much of the latter tends to flatness.

For fine gradation and delicate greys in the half-tones the formula is:—

## Formula D.

Distilled water .....	1 oz.
Citrate of iron and ammonia .....	18 grs.
Ferric oxalate .....	28 grs.
Oxalate of potass. ....	36 grs.
Chloride of copper .....	9 grs.
Oxalic acid .....	16 grs.
Silver nitrate .....	18 grs.
Gum arabic .....	10 grs.
Bichromate sol., 5 per cent. ....	5 to 10 drops.

When too strong, the solution, as a rule, may be diluted; but if there should thereby be a debasement of the image a stronger developer should be used—a little more from the stock bottle.

In the presence of a great advance in the price of platinum, this particular kallitype process should find favour. Worked at its best, it is with difficulty distinguished from platinotype, and as for lasting qualities, it is as good as any other silver process, while more artistic than most of them.

In regard to successful working, a great deal depends on the quality of the ferric oxalate. It may be obtained of the leading chemical establishments in our larger cities; and when in prime condition should appear in shining greenish-brown scales. When at all powdery or matted together, with a tendency to cling to the sides of the bottle, it should be rejected as worthless for our purpose. Many failures in the process I am convinced might be traced to defective chemicals, more especially the ferric oxalate. In my own experience, I lately had to complain to the leading druggists in Boston of ferric oxalate obtained of them and found useless. In looking over their stock of this chemical they found all but a single ounce in the same defective condition. Still they had been selling from the stock all the time, and some experimenter may be wondering why he failed. Once you have bought the ferric oxalate, discard the shaved cork that comes with the bottle, and substitute one of the regular kind that has been soaked in hot wax. Keep the sealed bottle inside of an air-tight screw-top jar. Such jars as the housewife uses for preserving purposes are just the thing. Under such precautions the last few grains will be found in as perfect condition as the first.

Prints slightly over-exposed are just right for uranium toning, it having a somewhat reducing effect. This formula is as follows:—

Uranium nitrate .....	4 grs.
Ferriyanide of potass.....	4 grs.
Glacial acetic acid.....	16 drops.
Water .....	2 ozs.

Immerse prints, and rock until desired tone is reached; rinse and transfer to a tray of water in which there are a few drops of acetic acid. In running water, swab back and front, then wash for not over ten minutes; dry on blotters. In this bath brilliant reds should mature in about five minutes. In my own practice I seldom take the pains to measure the chemicals. I simply take some water in a tray and throw in a few grains each of the uranium and ferriyanide of potassium, with the addi-

tion of a few drops of acetic acid. All the reds are pleasing, and by varying the proportions of the chemicals a great variety of tones and colours are at our command. Swabbing the prints back and front is, I find, essential—particularly in the case of rough papers—to eliminate the sediment, which if permitted to remain, impairs the purity of the whites. If this system of toning is done as it should be there need be no complaint of impure whites, where the above precautions are observed and the prints are allowed to get bone dry before toning. This for some reason seems to be important, results not being as good otherwise.

While this entire process is simple enough, practice makes perfect here as in all else. The best of chemicals should be utilised, and the utmost cleanliness employed. The fingers are apt to become stained with silver, and prints should therefore be carefully handled by the edges. Marks from soiled fingers will produce yellow stains that no amount of washing can eliminate.

There is no doubt that the most beautiful pictures have been made by this process, and specimens were submitted to experts of national repute before venturing to publish the formula. My personal employment of the process being limited, it seemed to me a pity that all might not share in it; hence my giving it to the craft.

Failures no doubt there will be; but where so many different formulae are given as is here the case, they may be attributed to something outside of the process—defective iron oxalate, perhaps. Where this chemical is below the standard, fairly good prints may be had, but the deposit is scanty. There is, therefore, lack of richness in the shadows. In such a case the addition of from two to twenty drops of a solution of chloroplatinite of potassium will save the day. The smaller quantity will insure purple-black pictures of vigour, while the larger tends to reds.

Those having a taste for experiment may find some unusual effects by varying the proportions of the ingredients as here given. In Formula A the addition of from two to four grains each of the copper, silver, and the oxalic acid may be suggested for a trial where the blacks are not good, or where some other tones are sought. There is an exact excess of the silver that gives very pleasant sepia, but too much makes rusty shadows.

JAMES THOMPSON.

## PHOTOGRAPHIC PACKING PAPER.

In our last volume, page 404, we gave a sketch of the methods of testing raw papers for photographic purposes. An equally important point is the purity of the paper used for packing sensitive plates and papers, though the paper need not be of quite such expensive raw material, and, as pointed out in the "Wochenblatt für Papierfabrikation," it is usually made of wood pulp. This contains two principal substances, the cellulose, or cell substance, which is soluble in ammonio-oxide of copper, and the lignose, or wood substance, which is insoluble in the same. There may also be albumen, tannin, resin, starch, and colouring matter. The wood pulp is generally treated with hot lye to remove these; the subsequent processes of bleaching or colouring may, however, introduce other prejudicial substances. Although it is not so essential for the packing paper to be as pure as the other, yet it should be free from sulphites and hyposulphites as well as tannin and all other substances which would cause a reduction of the silver salts.

A simple experiment will prove whether a paper should be used or not. A few pieces should be boiled with distilled water, and to the filtrate should be added some drops of ammoniacal solution of silver nitrate. If the solution remains clear the paper is fit to use; if, on the other hand, a grey or black precipitate results it should be rejected. A test which even surpasses the last for delicacy is to cut a circle, triangle, or any figure out of the paper and place it in contact with the film of a very sensitive dry plate in a printing frame and keep in the dark for two or three weeks. On development with a solution that does not fog it will be easy to see whether an image of the piece of paper is impressed on the sensitive film. In all probability the prejudicial action is due to gases given off by the paper, and this can be proved by placing between it and the sensitive film a sheet of pure porous paper. As a rule it will be found that Swedish filtering, good tissue paper, and waxed tissue paper are the purest.

## THREE - COLOUR CAMERAS.

In devising the following camera for three-colour work, Herr Hans Schmidt, writing in our contemporary, "Photographische Rundschau," has kept in view two points—first, that to obtain instantaneous three-colour negatives it is absolutely necessary for all three exposures to be made at once, and secondly, that considering the existing panchromatic plates, it is essential that the picture which requires the longest exposure should receive the full action of light.

The use of more than one lens appears, therefore, to be absolutely essential, as this is obviously the most satisfactory method of attaining this end. In order, however, to practically do away with the stereoscopic difference it is necessary for the optical axes of the lenses to be as close as possible to one another. If the apertures of the lenses are chosen in the ratio of the exposures which the author sets down as 1:2:1, the largest aperture may be chosen as  $f/4.5$  and the others  $f/6.3$ . If also a focus of 5 in. be chosen, then the three lenses may be arranged as in Fig. 1, and the optical axes

enters the prism at 4, is reflected at 5, and again at 6, leaving the prism at 7 and produces the image U below  $A^1$ . A point R at one side of A emits a parallel ray which enters the prism at 8, is reflected at 9, leaves the prism at 10, and now forms an image at L, which is on the opposite side of  $A^1$ .

As the prism is a total reflection one, and transmits a large field of view, the images correspond in extent and illumination. Practical tests have shown that the camera works very satisfactorily. It is obvious that three lenses must have the same focus if prints are to be prepared from the negatives; if, on the other hand, chromosome pictures are to be made, this is not of so much importance, as their coincidence can be effected by altering their distance in the chromosome.

The numbers in Fig. 1 represent the distances between the lenses in millimetres.

M. GEISLER describes, in the "Photo Gazette," a new one-exposure

Fig. 1.

Fig. 2.

Fig. 3.

will be practically only 1 in. apart. This separation is so little that the stereoscopic difference, whilst theoretically existent, will not be practically seen, especially if one of the present three-colour printing methods be adopted.

By crowding the lenses together in this way the images will naturally be partially superimposed, and to avoid this, two of the images must be diverted by reflection. The use of mirrors or prisms between or behind the lenses is not new, but the disadvantages have been that the reflected images have been reversed. The introduction of a mirror between the lenses necessitates that the latter should be separated by a fairly wide interval, and with the modern anastigmats this only amounts to 1 or 2 centimetres, and it is therefore impossible; the reflecting surface must be placed behind the lens.

By the use of a special reflecting system shown in Fig. 3, it is possible, however, to reflect without inverting images, and without contracting the field of view.

The camera is shown in Fig. 2; the optical system consists of the three lenses A, B, C, and the two reversion systems D, E. M is the instantaneous shutter which covers all three lenses, whilst F, G, H are the three panchromatic plates and the filters in front of the same.

The light passing through the lens A proceeds direct to the plate G. By the combined action of the lens B and the system D, or the lens C and the system E, optical images are formed in F and H. These two images, in consequence of the peculiar action of the reversion systems D and E, agree in every point with that on the plate G, which is easily understood from a consideration of Fig. 3. From this it will be seen that a ray of light proceeding from A enters the prism at 1, is reflected from 2, leaves the prism at 3, and forms an image at A'. A point O lying above A emits a parallel ray which

three-colour camera, constructed by M. Nachet, the well-known optician, who was one of the first to make a chromoscope. Some years ago a company was formed to exploit a camera, which con-

Fig 4.

tained two platinised mirrors, placed at an angle of 45 degrees behind the lens; but this went into liquidation, because it was not found possible to obviate the reflection from the second surface of the mirrors, which gave double outlines to the images. This defect

has now been overcome by coating the mirrors with a coloured varnish.

The apparatus, Fig. 4, consists of a lens O, behind which is placed a small elliptical mirror M, the minor axis of which is about one-third the diameter of the lens, and forming an angle of 45 degrees with the axis of the lens. The central cone of rays contains all the image as well as the annular cone. The image reflected by M is received on the plate P<sup>2</sup>, and passes through the green screen E<sup>2</sup>.

The annular cone of rays is received by the sheet of glass E, whence it is reflected part to the plate P<sup>3</sup>, passing in its course through the blue-violet screen E<sup>3</sup>. The sheet of glass E acts as a mirror, and is coated with an orange-coloured varnish, which acts as the filter for the light passing through E to the plate P<sup>1</sup>. The

coat of orange varnish naturally extinguishes to some extent the duplicate image from the back of this glass plate E, and as also the duplicate image becomes a deep orange through its passing twice through the orange varnish, it is completely absorbed by the violet filter.

The dimensions of the elliptical mirror are so calculated as to reflect only the central cone of rays through the green filter, and the annular rays are partly diverted through the violet filter, while the other part passes direct through E to the plate opposite the lens, the ratios of the lights for the three plates being proportional to the actinic coefficient of the plates used.

Mr. F. E. Ives was the first, we believe, to use platinised glass for the mirrors, and he also obviated the duplication of the image by using coloured varnish, but on the back of the mirrors.

## THE SELECTION OF PLATES AND FILTERS FOR PHOTOMICROGRAPHY.

[The importance of orthochromatic work in photomicrography, the close attention of Messrs. Wratten and Wainwright, of Croydon, Mees, stating the principles upon which new filters, specially designed dyes, have been prepared. The instructions for their use appear to with Messrs. Wratten's consent we have quoted a large portion of

long recognised by expert photomicrographers, has of late received as a result of which a booklet has been issued by Dr. C. E. Kenneth to aid the reproduction of microscope specimens stained in the regular us so generally informing on this branch of photographic work that them below. —Eds. B.J.]

THE difficulty encountered by all photomicrographic workers in obtaining upon the photographic plate a proper and satisfactory contrast when dealing with stained sections of animal or vegetable tissue and more especially preparations of bacteria is very great, and many such objects quite baffle any attempt in making even a fairly good printable negative. The explanation is to be found in the fact that the dyes with which such objects are stained, though visually producing a striking contrast when examined in the microscope, do not affect the photographic plate in anything like the same degree, and although much may be done with the ordinary orthochromatic plates and screens now on the market, yet these fail in producing a negative that will satisfy the careful and earnest worker in this important branch of microscopy.

No text books on photomicrography give any definite instructions, and the worker is always in doubt as to what screen is required for a certain colour. The following notes and instructions combined with the use of our plates and screens will, we venture to think, be found sufficient to enable the photo-micrographer to obtain records of objects that he has long given up in despair.

A table is given below that will enable one to tell at a glance just what screen and plate to use for a given stain. The troublesome, uncertain, and "messy" liquid screens are done away with, our series of screens can be used in the ordinary screen holders or can be cut into circles and used in the patch-stop carrier of the sub-stage condenser of the microscope, which is no doubt the best position. Another important point is that by using a proper screen the resolving power of the ordinary achromatic micro-objectives is much improved and will make their performance almost if not quite equal to that of the more expensive apochromatics.

### Principles.

There are two main principles to be kept in mind.

- (1) The light used should be as nearly as possible monochromatic, that is should consist of homogeneous light of one colour only.
- (2) The light used should be in the *absorption region* of the stain; that is, should be complementary in colour to it.

When speaking of the light used it must be remembered that this means the *light acting on the plate*; not the light visible to the eye.

With regard to these two principles.

- (1) Any objective will give better definition when used for monochromatic light than for polychromatic, and in the case of objectives with any but the most perfect chromatic correction the improvement is most noticeable.
- (2) If light corresponding to the absorption region of the stain be used then the stain will be as dark as possible, and the greatest possible contrast in lighting will be obtained.

### The Nature of Light.

In order to make this point quite clear, the following explanation may be useful:—White light may be regarded as being made up of light of various colours, and by different devices may be split up into these colours. When this is done, there is obtained what is known as the spectrum.

Light is found to consist of waves of different lengths, different lengths corresponding to different colours, so that the spectrum corresponds to a scale of different length waves. The length of a light wave is the distance from the crest of one wave to the crest of the next.

The following diagram gives a simple arrangement of the spectrum, the numbers representing the length of the waves and the colours being placed close against them:—

It will be seen that the visible spectrum extends from 7,000 to 4,000, and is equally divided into regions which may be broadly termed:—

Red	7,000—6,000
Green	6,000—5,000
Blue Violet	5,000—4,000

### Absorption Spectra.

Now if we take a solution of methyl violet and examine the spectrum of a light source through it, we shall find that the whole region between 4,600 and 6,200 is absent, that is to say, *methyl violet has an absorption band extending from 4,600 to 6,200.*

Consequently we shall fulfil both the principles given above if we photograph a methyl violet stained section with monochromatic light (principle 1) of wave-length anywhere between 4,600 and 6,200. But if we dilute our solution of methyl violet, we shall find that as the solution grows weaker, the absorption band narrows until with very weak solutions the only remaining trace of a band is from 5,800—6,000.

So that if we are to fulfil condition (2) for sections very weakly stained with methyl violet, our monochromatic illumination must be as near as possible to 5,900.

### Practical Instructions.

The chief microscopical stains have the following maxima of absorption, and consequently require illumination in those regions. The column at the side gives the plate and screen which will give those

illuminations. The screens referred to are the Wratten Photo-graphic screens (M series).

Stain.	Spectral Absorption Bands.	Plate and Screen.	Band used.
Aniline blue .....	57-60 ...	Allochrome E .....	56-59
		Verichrome or	
		Panchromatic E & B .....	56-60

FIG. A.—Whalebone Section (light brown) photographed for contrast, I.D.S. plate and D screen.

In order that the reasons for using the above plates and screens may be clear, it must be understood that the Wratten plates record follows:—

I.D.S. ....	From Ultra-violet to 50
Allochrome .....	and 54-59
Verichrome .....	Whole Spectrum to 64
Panchromatic .....	Entire Spectrum to 69

The Wratten M Screens have the following transmissions:—

A .....	From red end to 59
B .....	60-46
C .....	52-40
D .....	Red end to 64 and 46 to Ultra-violet
E .....	Red end to 56†
F .....	Red end to 61 and 46 to Ultra-violet
G .....	Red end to 51
H .....	54 to blue end
K3 .....	Luminosity screen for correct reproduction

So that taking a few typical stains from the list given, we have Aniline Blue with an absorption band from 37-60, photographed

For photography by transmitted light, see "Uniformly Coloured Sections." When are lamps are used, Screen E transmits the ultra-violet, and G must be used to cut it out.

with screen E. Screen E transmits from Red end to 56, but the Allochrome is only sensitive to 59, so that the Aniline blue is photographed with the narrow band from 56-59 and in its absorption band. Methyl green has an absorption band from 62-65. Photographed

FIG. B.—Whalebone Section photographed by transmitted light, Verichrome plate, F & G screens.

with screens F and G which transmit from red end to 61; but the Verichrome is only sensitive to 64, so that the methyl green is photographed by the narrow band from 61-64 in its absorption band.

It is not forgotten that the resolution of an objective increases in proportion to the shortness of the light waves, so that for extreme

Aniline blue stained Section (very faint), photographed with Allochrome plate and E screen.

resolution it is necessary to use light below 30 if possible, but in ordinary work this is negligible in comparison with the importance of obtaining sufficient contrast.

By using these screens together the spectrum can be divided up into monochromatic portions thus:—

A & D .....	Red end to 64
A & F .....	" " " 61
A & B .....	60-58
B & E .....	60-55
C & G .....	51-52 (very dark)
G & H .....	51-54
B & C .....	46-51
D & H .....	46-40

Inner cells stained with methyl green, outer picro-carmine, photographed with Allochrome plate and E screen.

If the best results for a particular section cannot be obtained by following the instructions, then the section should be examined

visually with the above combinations of filters until that filter is obtained by which the portion which it is desired to photograph shows the greatest contrast compared with the field. If that filter is then employed for photographing, the best possible result will be obtained.

#### Uniformly Coloured Sections.

There is one type of section which requires entirely different treatment, because principle (2) does not apply.

In some cases, notably large insects, we have a wholly coloured field without any clear glass in it, and it is required to obtain detail in this coloured field.

In this case photography must be done in the region transmitted, not that absorbed. Thus, in figure (a) we have a section of whale bone which has been photographed in its absorption region, and shows the maximum contrast. Figure (b), however, shows the same section photographed in its transmission region by means of a Verichrome plate and F and G screens, giving all the detail of the section.

For insects and yellow sections generally photograph—  
For contrast, with an I.D.S. plate and D screen.

For detail in the section, with a Verichrome plate and F and G screens.

## MODELS OF LENS ABERRATIONS.

[The following communication to the "Photographic Journal," by Mr. C. Welborne Piper, gives a description of the models of lens aberrations shown at the last exhibition at the New Gallery, and awarded the only medal in the Technical Section.—Eds. B.J.]

THESE models, which are now in the museum of the R.P.S., were made some time ago for the purpose of studying the structure of a light pencil with a non-spherical wave-front; that is, such a pencil as is formed by a lens corrected for chromatic aberration alone, or by a simple positive lens when the light is monochromatic. The first thirty models are accurate representations made with the aid of an 8-in achromatic meniscus lens; as, however, such a lens does not produce all the varying effects possible, the series illustrating "Coma" is complete only for this particular lens. Other varieties of coma exist, hence the models must not be considered to give a complete analysis of the subject. The last ten models illustrating astigmatism are also incomplete. They simply represent the forms of astigmatism left when the fundamental cause of the coma, existing in the other models, is removed. They therefore only illustrate a hypothetical case, and though this is one of considerable theoretical interest, it is not typical of the effects of astigmatism commonly met with.

The classification of the aberrations that I adopted when labelling the models is incomplete also, owing to the limited conditions observed. Later work has shown that a certain feature of the particular coma pencils studied, which at the time was merely noted as an interesting characteristic, is most probably a special feature that is responsible for certain of the effects in the coma models and possibly productive of a different variety of astigmatism.

The manner in which the models were made has already been described in this "Journal," at page 341, in the issue for November, 1906, and need not be repeated; a description of the classification and of the terms used on the labels is, however, desirable.

In constructing the models, the light pencils were analysed in the following way. A plate perforated as shown in the figure was placed in front of the lens to serve as a diaphragm. The central aperture then transmitted the "chief ray" of the light pencil, and the perforated "Zones" and the "Radial Sections" (AB, CD, EF, etc.) transmitted a skeleton pencil that could be studied and mapped out in detail. In the case of oblique or eccentric pencils the plate was arranged so that one radial section, AB, coincided with the primary plane of the pencil, this section thus becoming the "Primary Radial Section." The radial section CD was then in secondary plane and became the "Secondary Radial Section," while any other radial section, such as EF, was simply styled a diagonal radial section. The light passing through any one of these radial sections forms a "Chief Section" of the light pencil, this term being adopted because all such chief sections contain the chief ray, which is common to all. According to the radial section from which any chief section originates so such chief section is styled Primary, Secondary, or Diagonal. The Primary chief section is invariably a plane, coincident with the Primary plane of the pencil. The other chief sections are not necessarily planes and therefore do not always coincide with the corresponding Secondary or Diagonal Planes, which are datum planes only. Excepting in the case of a pencil quite free from coma, these other chief sections are winding curved surfaces of interesting form, and a series of them is to be found in model B. These surfaces are of course subject to modification in the case of other lenses showing other varieties of coma.

The light passing through any one zone of the diaphragm plate forms a hollow "Zonal Pencil," which in the absence of either coma or astigmatism is conical in form. In the presence of either of these effects the zonal pencil has an intricately curved envelope that can only be perfectly shown in a model. Various specimens of zonal pencils are to be found in the models.

A transverse section of a zonal pencil gives a "Zonal Section." Examples of such sections will be found in models 27—29 D, at 38—40 F, others will be found in Professor Sylvanus Thompson's

Traill-Taylor Memorial Lecture on "Zonal Aberration," and in M. Dennis Taylor's "System of Applied Optics." The effects illustrated in the models are those commonly known as Central Aberration, Coma, and Astigmatism. These terms I have used simply to describe the effects produced on the image screen. I do not look upon these effects as separate "aberrations" because analysis shows that the latter two effects are usually very complex, and due to several distinct defects in the structural formation of the light pencil. The term "aberration" I have applied only to the structural defects that ultimately cause the effects styled coma, etc., and in the models three such defects or "aberrations" are mentioned, under the names of "Longitudinal Aberration," "Lateral Aberration," and "Radial Aberration." In the models the existence of the three aberrations mentioned is very obvious, and they may be described as follows.

Reference to Fig. 1 will show that a perforated plate such as that shown divides the large pencil into a number of small beams that may be styled rays for the sake of argument. If we consider only such perforations as mark the intersections of the various zones and radial sections we can exactly define any one ray by describing the zone and section to which it belongs. Thirty-three

rays, including the chief ray, can be thus defined from the diaphragm shown. If the lens is perfectly corrected it is obvious that all these rays must meet in one point or focus, but if aberration exists this condition will not be fulfilled. Certain rays will meet one another and form foci, but these foci will be displaced in various directions from the one position that they should occupy in the perfect pencil. If the intersection of any two rays is styled a focus it is obvious that the number of foci formed in a complete pencil is infinite, and a very large number may exist even in a skeleton pencil of only thirty-three rays. It is, however, only necessary to consider a limited number of such foci in order to classify the various degrees of displacement to which they are subject, and so distinguish the separate aberrations.

The possible foci may be divided into "true foci" and "false foci," the former being the foci or intersections of rays belonging to the same zone and same radial section. In the diagram a true focus will be formed by rays passing through A and B, C and D, E and F, of c and d, but A, E; A, F; or C, d, for example, will make false foci. In the classification adopted in the models I ignored displacements of false foci and considered only those of the true foci.

In the perfect pencil all true foci coincide and the following conditions prevail:—

1. All true foci are on the chief ray.
2. All true foci belonging to any one zone are equally distant from the lens.
3. All true foci belonging to any one radial section are equally distant from the lens.

In the imperfect pencil the true foci may be displaced laterally off the chief ray, in which case we have "Lateral Aberration," which is the fundamental defect that causes the unsymmetrical effect known as coma.

Again, the true foci belonging to one zone may not be equally distant from the lens; thus AB may have a nearer focus than CD. If this is the case then different radial sections in the same zone give "true foci" that are separated longitudinally from one another, and "Radial Aberration" exists. This is the fundamental defect that causes the effect called astigmatism.

Again, the true foci belonging to any one radial section may be at different distances from the lens. The different zones in one radial section then give true foci separated longitudinally from one another. In this case a form of "Zonal Aberration," distinguished as "Longitudinal Zonal," or simply "Longitudinal Aberration" exists. This is the prime defect that causes the appearance of "Central Aberration," sometimes called (but I think misnamed) "Spherical Aberration."

The coma models all show a very complex effect due to all these aberrations. If all traces of lateral aberration are eliminated from these models, a mixture of longitudinal and radial aberration is left, which is styled "Mixed Astigmatism" and is illustrated in some of the models. If from the mixed astigmatism the longitudinal aberration is removed radial aberration alone is left and "Pure Astigmatism" appears. This is also illustrated in the models, and the peculiar effects shown at the foci are inevitable unprovided radial aberration exists alone. In this pure astigmatism the primary and secondary "focal lines" are represented by figures of eight, while the mean focus is a cross. In the mixed astigmatism the same forms exist in individual zonal pencils, but those belonging to any one zonal pencil are obscured by the other zonal pencils, which owing to the longitudinal aberration are all in different phases at any one particular distance from the lens. The primary and secondary foci then become ovals, while the mean focus is an approximate circle. Another form of astigmatism is possible, but this cannot be caused by pure radial aberration alone, nor yet by a mixture of radial and longitudinal aberration, and is not shown in the models. The astigmatism actually found in photographic lenses seldom appears to resemble any of the hypothetical forms. It is often modified by varieties of lateral aberration and many of the effects observed are very complex. Accurate models of the existing forms have not yet been attempted.

If longitudinal aberration exists alone, central aberration appears. This is commonly only observed in centrally incident direct pencils. The slightest degree of eccentricity or obliquity at once introduces lateral aberration, which is almost invariably accompanied by

radial aberration. The lateral aberration thus introduced varies in direction. With a positive uncorrected lens of meniscus form with concave side towards the object, simple obliquity of incidence always produces outward coma, or lateral aberration in the direction in which the emergent pencil is swung. Simple eccentricity produces lateral aberration in a direction opposite to the eccentricity, and as this may be in either of two opposite directions the effect of eccentricity may tend to either re-inforce or to partially counterbalance that due to obliquity. This is shown in models 4 to 7A.

These models represent work that was carried out over four years ago, and the classification given above is not quite the one I should adopt to-day. It is, however, necessary to describe it if the labels on the models are to be understood, and even though the classification and nomenclature be imperfect according to present day views the accuracy of the models is in no way affected.

It should be noted that the classification is imperfect owing to the fact that it considers the displacement of "true foci" alone. A complete analysis would also consider the displacement of certain "false foci," which defects exists in the coma models, and is one of the causes of the "linear astigmatism" shown by spherocylindrical lenses and sometimes by combinations of spherical lenses. In this variety of astigmatism the primary and secondary foci are lines and the mean focus is an approximate circle. No cross is formed, but with photographic lenses traces of the cruciform "pure" variety can often be observed.

C. WELBORNE PIPER.

#### THE ROYAL PHOTOGRAPHIC SOCIETY.

The annual meeting of the Royal Photographic Society will be held on Tuesday next, February 12, when the election of officers by ballot for the present year will be announced and the report of the council and the balance-sheet presented. The ballot-paper now with the members is to be returned to the secretary at 66, Russell Square, not later than Monday next, February 11. The Council's report already circulated among the members is repeatedly apologetic in its tone, although in some particulars—e.g., the accession of new members—the past year of the society has been one of progress. The following few items, selected from the documents which have been issued, will no doubt be discussed at the annual meeting:—

There is a deficit of £94 on the year's working.

The Journal of the society has been published at a loss of £222, an increase of £25 on 1905.

The alterations to the lecture-room, placed to the capital account, amounted to £406.

The profit on the exhibition was £106, compared with £166 in 1905, the difference being due to the greater expenses necessitated through the society's house being in the hands of the builders.

Members to the number of 67 showed at the exhibition, the remainder of 174 being non-members.

#### DR. KORN'S TELECTROPHOTOGRAPHY IN PARIS.

Last Friday, February 1, at the offices of the Parisian journal, "L'Illustration," Professor Korn gave a demonstration of the telegraphic transmission of images, the accounts of which have already appeared in our pages. The event was made the occasion of a public function by the proprietors of "L'Illustration," to whom the sole rights in France of the Korn system have been ceded by the inventor. A large number of representative men were present, including M. Louis Barthou, Minister of Public Works, and M. J. Simyan, Secretary of the Postal and Telegraph Department, with numerous members of the French Chamber and of the Press. We noticed among the six hundred visitors Le Prince Roland Bonaparte, M. Faurès, M. Santos-Dumont, and M. Nadar.

Dr. Korn, speaking in almost perfect French, gave a brief address on his invention, illustrating the results which had been obtained by projection on the screen of portraits, transmitted a few days previously over a circuit of 1,500 kilometres. Among the portraits were those of the Prince Regent Bavière, of M. Poincaré, the mathematician, and of M. J. Carpentier, member of the Bureau of Longitudes. Lastly, the appearance of a portrait of His Majesty King Edward, who that evening had arrived in Paris, was the signal for a round of applause.

The meeting then proceeded to witness the transmission of the

portrait of M. Fallières, over a circuit from Paris to Lyons and back, a distance of 1,024 kilometres, the outward and return wires being those of the Central Telephone Company of Lyons. The receiving instrument was placed a few yards from the transmitter, and the portrait which we reproduce was obtained in six minutes. The dimensions of the largest picture which can be transmitted are 18 x 24 cm., the transmission taking place at the rate of one minute

Reproduction of the portrait of M. Fallières telegraphed from Paris to Lyons and back.

per square centimetre, at a speed of rotation (of the cylinder of the machine) of ten revolutions per minute. The demonstration was directed by M. Carpentier and Herr Wilm, Dr. Korn's assistants.

The demonstration was not without its humorous incident, for the telephone operator "cut off" the connection during the progress of a transmission, with the result that the portrait showed a white line along its length.

Apparatus for the continuous working of the instruments between Paris, Berlin, London, and Munich are in course of construction by M. J. Carpentier.

## Photo-Mechanical Notes.

### The Levy Acid-Blast Etching Machine.

A recent patent (No. 18,869, 1906) taken out by Louis Edward and Max Levy, of Wayne Avenue, Berkley Street, Philadelphia, U.S.A., describes certain improvements in the machine, which has become known in this country and is already in use in the establishment of at least one photo-engraver. Means are now provided whereby the etching-chamber is provided with aspirators for the removal of the gaseous but condensable products which result from the action of the etching fluids in the metal plates. The general construction and action of the machine will be clear from the following figure and description:—

The etching fluid is placed in the etching-chamber (15) in sufficient quantity to cover the lower portions of the aspirators, the carriage having the plate to be etched attached thereto is moved to occupy a position above the etching-chamber, and is connected to the hook 44, and when power is applied to the shaft 37 the carriage and its attached plate will be reciprocated. The pump or blower (30) being driven forces air into the compartment below the etching-chamber, and such air under compression escaping through the aspirators projects the etching fluid in the form of atomised spray

against the reciprocating plate. The chemical action of the atomised erodent upon the unprotected parts of the plate evolves fumes, heat, and gases, all of which augment the contents of the etching-chamber, and to prevent such fumes and gases escaping and vitiating the atmosphere about the machine and to recover a part of the etching fluid, the vapours along with the fumes and gases are drawn from

the etching-chamber by the pump or blower, effecting a partial vacuum in the etching-chamber, the reduction of pressure causes an inflow of air into the etching-chamber about the edges of the covering plate. The products that are drawn from the etching-chamber by the pump or blower pass about a series of baffle plates, the vapours being condensed flow back into the etching-chamber. The plate after being etched is moved over the washing-chamber and is washed by water that is projected upward through the nozzles attached to the bottom of the washing tank.

### Ippertype-Transfers of Resists to Metal Plates from a Relief on Flexible Film.

A very lengthy patent specification (No. 26,965, 1905) has been filed by John William Ippers, 101, Beekman Street, New York, U.S.A., for a process of preparing rotary metal printing plates by the following process:—

- (1) Making a sensitive gelatine plate on a flexible celluloid base, having a gelatine coat of uniform thickness.
- (2) Exposing the gelatine plate to light through a negative.
- (3) Developing the plate by bathing it in water, and thereby making numerous irregular and irregularly-distributed cracks in its surface.
- (4) Drying the plate in air and applying glycerine solution to those parts of the surface which will take it.
- (5) Applying ink to the other parts of the surface and transferring the ink to the periphery of a metal roller.

### "Klimesch's Jahrbuch," 1906.

This annual, which is somewhat on the lines of Penrose's "Process Year Book," has lately reached us. It differs from the latter, inasmuch as there is consideration of book printing, as well as process matters. There are twenty-seven articles, most of them are of a somewhat solid character. Of these more than half deal with printing or allied subjects, the remainder are concerning photo-mechanical processes, the chief perhaps being one on the preparation of screen negatives by means of collodion emulsion, for three and four-colour work, an article that runs to fifteen pages. Two useful articles always contained in this year-book are a list of the technical books published during the year in Germany and a list of the patents granted by the German Government in the particular classes concerning photography and the printing press.

The supplements are not bewildering in number and variety, as there are only twenty-seven of them, but they are excellent of their kind, chiefly three and four colours, and some good collotype. Except for the binding, the wire stitching, and some of the ornament used, the get-up is very tasteful, a calendered paper is used, not a clay surfaced art paper, and the type is good and readable.

### PHOTO-MECHANICAL PATENTS.

The following patent has been applied for:—

MOUNTING BLOCKS.—No. 709. Improvements in mounting blocks for printing plates. Albert Waters Harrison, 7, Southampton Buildings, London.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following Patents were applied for between January 21 to January 26:—

**SHUTTERS.**—No. 1,487. Improvements in appliances for automatically operating the shutters of photographic cameras. Edward Geisler Herbert, 89, Northern Grove, West Didsbury, Manchester.

**ELECTROPHOTOGRAPHY.**—No. 1,548. Improvements in tele-automatographic systems. Arthur Korn, 133, Fleet Street, E.C.

**POSTCARD PHOTOGRAPHS.**—No. 1,617. Improved method of attaching photographs to postcards. Thomas Clegg, Park Studio, Rawtenstall.

**STEREOSCOPY.**—No. 1,763. Improvements relating to stereoscopy. Gilbert Arden Shakespear, 18, Southampton Buildings, London.

**TRIPODS.**—No. 1,787. Non-slipping shoe for photographic and other tripods. Alfred William Stainton Sanderson, Mossburn Buildings, Altrincham.

**SHUTTERS.**—No. 1,849. Improvements in focal plane shutters or other roller blind photographic shutters. Arthur Lewis Adams, Birkbeck Bank Chambers, Southampton Buildings, London.

**PRINTING PAPERS.**—No. 1,883. Improvements connected with photographic printing papers or surfaces. John Page Croft, 11, Burlington Chambers, New Street, Birmingham.

**STEREOSCOPES.**—No. 1,926. Improved stereoscope. William Arthur Phillips, 4, South Street, Finsbury, London.

**PHOTOGRAPHS IN GLASS.**—No. 1,928. Improved process for producing photographs on metal, glass, porcelain, etc. Alfred Hans, 58, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**DEVELOPING APPARATUS.**—No. 1,037. 1906. The claim is for a combined camera and developing chamber, capable of containing a change of plates or films, of exposing the same, and of transferring them to a chamber for development without handling them or detaching them from the apparatus. The apparatus is thus, first, a wrapper for the plates; second, a light-proof vehicle for charging and unloading the camera with the plates; and third, a light-trapped sheath which enables the plates to be developed and fixed without removing them therefrom. Arthur Augustus Brooks, "Cranleigh," Park Avenue, Ashton-on-Mersey.

The following complete specification is open to public inspection before acceptance under the Patents' Act, 1906:—  
**FILMS.**—No. 1,454. 1906. Manufacture of films for photographic and other purposes. Smith.

## New Trade Names.

**ANNO.**—No. 288,760. Photo-engravers, sensitive compositions, being chemical substances, included in this class. The British Gelatine Works, Ltd., New Bedford Road, Luton, gelatine manufacturers. December 11, 1906.

**OPTICLUX.**—No. 2,881,529. Photographic and microscopic lenses and prisms. W. Watson and Sons, 313, High Holborn, London, W.C., opticians. December 4, 1906.

Under the name of "Chromograph" a system of trichromatic colouring is being worked by Mr. Henry Hawkins, York Road, Ilford, by whom portrait or landscape prints will be coloured for professional photographers. Unlike other systems, resembling "chromograph" as described, the results of the process are free from excessive brilliancy and, in certain of the specimens submitted to us, harmonious in colouring. Mr. Hawkins offers to supply a single cabinet from any negative for 2s. 9d. mounted ready for showcase, post free, or 2s. each for not less than six copies. He is also open to demonstrate the process for a fee.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Print Trimming.

In cutting very thin papers (writes Mr. C. H. Hewitt in last week's "Photographic News") the principal danger lies in the paper first slightly buckling under the forward movement of the knife, the alternate slight buckling and cutting resulting in an irregular or wavy edge. Three conditions are necessary to avoid this. The first is a very keen edge on the knife, so that the blade will cut without pushing the paper before it. The second is a very clean square edge on the steel triangle, so that the paper is held close up to the cut. The third is a cutting plate which is absolutely flat, ensuring the paper being nipped tightly between the true edge of the triangle and itself. If the sheet of zinc recommended for general use gets at all out of the flat, a sheet of cardboard may be employed for this special work, and, being slightly yielding under pressure, the thin paper is more firmly held at its edge.

### Pictorial Postcards.

A stationer on the South Coast (writes "F. M. S." in Tuesday's "Amateur Photographer.") has said that during the past year he has sold no less than 100,000 postcards. At first sight it would seem that his profit on such a quantity would be enormous, but when the figures are looked into, the profits are very small.

Putting the hundred thousand at one penny each—perhaps too high a figure, for in many towns they are sold at five and six a penny—we have a total of £416 nearly. Against this must be put the cost of the cards, rent of shop, wages of assistants, and depreciation of stock: say, £100 for cost of cards and envelopes; £100 for rent of shop, gas, etc.; £75 for wages; £25 for depreciation, and we have a profit of £116.

To sell 100,000 cards in three hundred and eight days, they must be sold at the rate of three hundred odd a day, or nearly two in every three minutes of an eight-hour day.

The amount, £25, for depreciation may seem high, but many subjects soon become stale and become unsaleable; then many buyers forget to pay for what they buy.

Whether £75 is enough for wages depends on the market value of human flesh. One person would have to attend to the sales and another to the buying. If the latter is not most carefully attended to, the stock would soon become far too large. Then when the mania exhausted itself, the stationer would find himself burdened with many hundredweights of waste paper.

### Night-lights for Ruby Lamps.

Like many others (writes Mr. W. A. Grosvenor, in "Focus"), I have tried numerous contrivances, both in the shape of lamps and in different kinds of illuminants. The "night-light" proved to be the most handy in every way, being extremely portable, and when burnt in a glass cup was most cleanly and safe. There was only one drawback. The light given was hardly sufficient. As an experiment, I drew out the wick, replacing it by a larger in the shape of a wax vesta, and the result was a larger flame, and a capital light. Here, I concluded, if only a larger wick were inserted in the ordinary night-light, was an ideal light for the photographer. So I wrote to Messrs. Field, of London, of "Ozokerit" fame, and mentioned the suggestion. To my pleasant surprise, I discovered my idea had been already acted upon, for in reply to my note Messrs. Field informed me that they had for some time been making special lights for photographers on the night-light principle. These are in a casing of thin lead, with a wick which gives a good flame. I immediately tried one of them, and at last found what I had long sought after—a good, reliable, safe, and portable dark-room illuminant.

### CATALOGUES AND TRADE NOTICES

"Thornton-Pickard Novelties."—An abridged catalogue has been issued under this title by the Thornton-Pickard Manufacturing Co., Altrincham. It lists the latest of the firm's introductions in cameras, including the "College" set of remarkable value, the new "Automat" camera, and the folding "Ruby" hand stand camera, an instrument of the most universal type, if that phrase may be admitted.

On Monday next, February 11, a fortnight's clearance sale opens at Messrs. Marion's. The full catalogue published yesterday should be applied for by those desirous of securing bargains in lenses, cameras, mounts and sundries, of which Messrs. Marion offer a large variety.

## New Books.

"Photography for Students of Physics and Chemistry." By Louis Derr. 247 pages; 7 x 4½. London: MacMillan and Co. 6s.

The writer of this text-book is associate professor of physics in the Massachusetts Institute of Technology, in which position he has delivered courses of lectures on the principles of photography to students in the chemistry and physic classes. The volume, which has grown out of these lectures, aims at stating the theories of photographic processes in an elementary form capable of assimilation by those who have had some scientific training, but not very much of it. Hence the book is not an instruction manual, of which there are already too many, but a discussion of the broad principles underlying photography, of which there are too few. Professor Derr thus approaches the reader as a person who wants to know the reasons for certain photographic procedure and the main facts upon which photographic processes and the construction of photographic apparatus are based. He devotes more than one third of his space to the lens and the camera, and gives a very clear and uninvolved explanation of the principle of a lens' action, and the means of eliminating the chief aberrations from a lens. The chapter on "Classes of Lens" presents as good a review of the latter achievements in photographic optics as could be desired and the explanation of lens terms which are given *en passant* should be appreciated by the student to whom the subject is strange.

In treating of development he classifies methods of rendering visible a latent image, in regard to which it is somewhat confusing, we think, to speak of potassium oxalate in the platinotype process as a "developer" analogous to an acid solution of iron salt for the wet collodion plate. The later discussion, however, of the work of Hurter and Driffield and Watkins, is excellent, though later on we come to a curious typical developing formula with sodium phosphate in it. The author gives no reason for instancing the presence of this substance, and the selection of a special formula must prove puzzling to the reader who endeavours to discover the function of each constituent in it. Later still, we are told in the same chapter that the ferrous oxalate developers must be made up at the moment of use. Yet these minor slips do not detract from the total usefulness of the book not only to students of physics and chemistry, but to the photographer who, knowing a good deal of the practical side of photographic processes, desires to systematise his knowledge and to carry out his practice more intelligently. The volume shows marks of its American origin in the spelling of "center" and other words, and the use of the word "kit" in its transatlantic sense—that of carrier for a small plate in a larger dark-slide.

"GUIDE du Photographe Debutant."—A little brochure of 35 pages has been issued under this title by MM. Gautier and Villars at 75 centimes. It is from the pen of M. C. Fabre, and briefly introduces the photographic beginner to the essential preliminaries to his hobby.

MESSRS. RAYNER AND Co., patent agents, 37, Chancery Lane, London, W.C., send us the completion of abridgments of specifications in Class 98 (photography) which they have been issuing, with an indication of those patents which have become void. This additional information adds to the value of the official records, and Messrs. Rayner's labours have our commendation, if only for the reason that they have frequently been of service to ourselves.

THE South London Exhibition.—The last day for pictures, we would remind our readers, is February 16.

THE Lancashire and Cheshire Photographic Union has published its 1907 year-book, containing the rules and objects of the Union and a list of the societies in it. The term "affiliated" used in the year-book is apt to cause confusion, we are afraid, particularly as the cover of the year-book is an almost perfect match to that of the affiliation "Red Book." The many lecturers and lectures which the Union can "present" are also listed. We congratulate the Union on the strength it has now attained for forty-two societies and 3,300 associates.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### FRIDAY, FEBRUARY 8.

Cardiff Photographic Society. "Gwbert" D. Till.  
Photographic Society of Ireland. "Light and Shade." James Brennan.  
Wallington Camera Club. "Denizens of the Deep." F. Martin-Duncan, F.R.P.S.  
Hamstead Scientific Society. "Bird Stations of the British Isles." Herbert Goodchild, M.B.O.U.  
St. Albans Photographic Society. "Sports and Pastimes with the Goerz-Anschütz Folding Camera."  
Oliver Goldsmith Photographic Society. "What Can be Done with a Hand Camera." C. P. Goerz.  
Marple Camera Club. "Postcard Photography on 'Rotograph' and 'Rotox' Postcards."  
Sutton Photographic Club. "Architectural Photography." C. J. Marshall.  
Whitby Camera Club. "Theory and Practice of Self-Toning Papers."

#### MONDAY, FEBRUARY 11.

Derby Photographic Society. "President's Holiday Rambles with a Hand Camera." E. Collier Green.  
South London Photographic Society. "Stereoscopic Photography." H. Creighton Beckett.  
Lancaster Photographic Society. "Bromide Toning." A. Davies.  
Oxford Camera Club. "Combination Enlarging." John H. Gear.  
Preston Camera Club. Exhibition of Members' Work in Club Rooms.  
Southampton Camera Club. "Gloucester Cathedral." Illustrated. Harold Baker.  
Wolverton Camera Club. "Enlarged Negatives on 'Rotograph' Negative Paper."  
Central Photographic Society. "Ozobrome." Dr. J. H. Wilson.  
Wellcome Photographic Club. "The Photographic Lens." C. P. Goerz.

#### TUESDAY, FEBRUARY 12.

Royal Photographic Society. Annual General Meeting.  
Burton-on-Trent Natural History and Archaeological Society. "The Carbon Process." E. Abrahams.  
Leeds Photographic Society. "A Chat about Hand Cameras." Illustrated. A. M. Nicholson.  
Keighley and District Photographic Association. "Glimpses of Life and Scenery in Switzerland." P. Lund.  
Hackney Photographic Society. "A Cornish Holiday." W. A. Furze.  
Manchester Amateur Photographic Society. Lancashire and Cheshire Photographic Union Lantern Slides and Folio.  
Trove Camera Club. Lecture and Lantern Slide Competition.  
Darlington Camera Club. "Preparing the Exhibition Print." C. J. Barthorpe.  
Nelson Camera Club. "Enlarged Negatives on 'Rotograph' Negative Paper."  
Birmingham Photographic Society. Exhibition of Post Cards.

#### WEDNESDAY, FEBRUARY 13.

Central Technical College Photographic Society. "Astronomical Photography." Prof. E. Walter Maunders, F.R.A.S.  
Edmonton and District Photographic Society. "Figure Study." E. T. Holding.  
Woodford Photographic Society. "Preparation of Negatives for Printing." E. H. Carpenter.  
Borough Polytechnic Photographic Society. "The History of Photography." W. F. Notman.  
Leicester and Leicestershire Photographic Society. "Home Portraiture." D. C. Uquhart.  
North Middlesex Photographic Society. "Ozobrome." T. Manly.  
Hertford Camera Club. "Contact Printing on Rotograph Bromide." The Rotary Company.  
Workshop and District Photographic Society. "Leading Features of Velox Manipulation."  
Birmingham Photographic Society. "Making Enlarged Negatives." W. I. Greatbatch.

#### THURSDAY, FEBRUARY 14.

Handsworth Photographic Society. "Tentative Development of Negatives on Unknown Exposures." F. E. Bill.  
L.C.C. School of Photo-Engraving. "Business Methods of American Photo-Engravers." Wm. Gamble.  
London and Provincial Photographic Association. "Lantern Slide Making (W. Plate)." H. C. Rapson.  
Hull Photographic Society. Members' Slides.  
Richmond Camera Club. "Exposures by Artificial Light." P. Payne.  
Blenheim Club. "A Further Account of My Three Years' Stay in Morocco." Illustrated. C. Rider Noble.  
Liverpool Amateur Photographic Association. "Lantern Slides" Demonstrated. F. G. Tryhorn.  
Windsor Camera Club. "Tabloid Brand Photographic Chemicals."  
Blackburn and District Photo. Society. "Enlarged Negatives on 'Rotograph' Negative Paper."  
North London Photographic Society. "Focal Plane Work." W. Kilbey.  
Kettering Camera Club. "What Can be Done with a Hand Camera." C. J. Goerz.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, February 5, Mr. J. C. S. Mummery in the chair. The second of the series of demonstrations of ancient photographic processes was given by Mr. Thomas Bolas, F.I.C., of "Talbotype." Mr. Bolas first exhibited a piece of the paper made by Turner in the fifties for the Talbotype process, its chief feature being evenness of texture. This property, he proved, had become totally destroyed by the decomposition of the sizing of the paper, for on immersing a piece of the paper in the iodising solution the latter penetrated quickly in some places and slowly in others, presenting a patchy effect. Modern thin Rives paper, the lecturer stated, would answer for the process. The first operation

consisted in saturating the paper with the iodising solution and removing the excess from the surface by pressing between blotting-paper. This process of complete saturation and subsequent removal of excess made the best of any irregularities in the paper, and was preferable to applying the solution with a brush. If a brush was used, one of the ordinary kind was useless for this, as for any photographic purpose where a clean chemical solution had to be applied, for the reason that the root of the brush retained traces of old or contaminated solution which could not be removed. In place of a hair brush, the so-called "Buckle brush," consisting of a tuft of cotton wool, drawn into a glass tube by a loop of string, was the best for the purpose, as it could be made new for each occasion of use by the provision of a new piece of cotton wool.

The iodising solution, the lecturer went on to point out, contained potassium iodide as its chief constituent, but it had also small quantities of potassium bromide and potassium iodate. This "compound" iodiser, as it was called, was prepared by the old Talbotype workers by employing the medicinal potassium iodide sold in large tube crystals and containing the above substances as impurities, whereas the purest iodide was obtained in a form, the crystalline shape of which could hardly be seen.

The sensitising of the iodised paper was done in a solution of the following composition:—

Silver nitrate .....	1 oz.
Water .....	8 ozs.
Acetic acid .....	1 oz. fluid.

This was contained in "dishes," which were made by the worker himself by cementing strips of glass round the edges of a glass plate with marine glue.

In place of the paper prepared in this way it was usual to iodise the paper, sensitise it, and then wash out the excess of silver solution so that the paper became practically insensitive. In this state the paper would keep for any reasonable time, and was "excited" at the time of use by immersing for a second time in the sensitising solution. It was exposed wet or dry. The lecturer prepared and exposed paper by both these methods, and in using a sample of old iodised and sensitised paper (method II.) explained that the darkness of its colour was due to the action of minute traces of iodine in the sensitiser on the starch in the size of the paper. The iodide of starch was, however, bleached at once by the silver solution. The exposed paper was developed in a solution of gallic acid, representing a strength of about 1 in 100. In this developed slowly, the operation requiring half an hour to an hour. The negative was then fixed in hypo in the ordinary way. This case of the waxed paper, which was used in order to secure greater transparency of the prints, the operations of sensitising and development occupied, in many cases, hours, and even days, in order to secure penetration of the solutions into the wax-coated surface of the paper.

Mr. Bolas exhibited a large number of specimens of Talbotypes and of Talbotype apparatus, including a Melhuish roll-holder, the prototype of the modern apparatus familiar to users of roll films. A hearty vote of thanks was passed to the lecturer on the proposition, who announced that the next demonstration would be of wet collodion, and by Messrs. Burton and Braham, of the Talbotype Company.

**SOUTHAMPTON CAMERA CLUB.**—The members of the above held a lantern slide competition on Monday evening last, the subjects being "Landscape and Still Life." Thirteen sets were sent in for a first, and a very popular award was secured by W. H. Triffin, one of the oldest of the club workers. Six sets were entered for "Still Life," and the award fell to H. Essex, with a couple of flower studies.

**BURTON PHOTOGRAPHIC CLUB.**—So considerable has been the awakening of interest on the part of local amateurs that during the last two years the membership of the club has more than doubled, consequently the meetings are now held weekly instead of fortnightly. That on the 25th ult. was devoted to a practical demonstration by the vice-chairman, Mr. A. P. Hoole, of the ozonem process, which he successfully demonstrated and explained. The 1st inst. a full exposition was given by the chairman, Mr. Hector Maclean, F.R.P.S., on "Modern methods of Mounting" to be reported in our next issue.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—At the meeting held on January 31, Mr. Ernest Human in the chair, Mr. A. H. Dunning lectured upon and demonstrated the new Wellington S.C.P. lantern plate. He said that the claim for this new plate was that, in addition to its being usable in an ordinary room, it was capable of rendering an immense variety of colours by development alone. At the same time it required more care in handling than did the paper of the same brand and make, and he recommended that it be shielded from the direct light when putting into the printing frame.

In place of the usual metol-hydroquinone developer he recommended and used the following:—

A. Water .....	20 ozs.
Hydroquinone .....	80 grs.
Soda sulphite .....	500 grs.
Soda carbonate .....	500 grs.
B. 10 per cent solution potass. bromide.	

The following table of colours is calculated for exposure to a naked incandescent gas burner at a distance of 12 inches:—

Tone.	Exposure.	Developer.
Black .....	15 seconds	A normal
Warm Black .....	30 "	Add 2 drops B to the oz.
Brown .....	60 "	" 3 " "
Warm Brown .....	2 minutes	" 6 " "
Red Brown .....	4 "	" 12 " "
Red .....	8 "	" 24 " "

Good tissue paper, he said, with ordinary mountant, made ideal slide binders, which were easy to put on, and, more than this, stopped where they were put, being far and away before the commercial article. He exposed the plates and produced both black and brown slides, using magnesium ribbon for the exposure, about  $\frac{2}{3}$  of an inch being used for the black toned slide.

A lively L. and P. discussion followed. Mr. Teape asked how long a red toned slide would take to develop, and upon being told ten minutes, offered a sixpenny bet that Mr. Dunning could not produce one in the time. The room being declared a place within the meaning of the Act, bets were inadmissible, but upon request from the chair Mr. Dunning attempted the task, using a foot of ribbon for his exposure. Upon measuring the bromide solution, however, he thought he had too much, and took half the quantity, the result being a warm brown fully developed in three and a half minutes. The chairman upon this likened the lecturer to the man who used an exposure meter, and then relied upon his own judgment, under-exposure resulting.

The chairman, in asking Mr. Stretton to move a vote of thanks, said that the members, at any rate, had taught the lecturer one thing, and that was that he could not produce red tones at command. Under new conditions Mr. Dunning, however, promised to work the red tones out with the ribbon, and let the Association know the exact result.

**SOUTH LONDON PHOTOGRAPHIC SOCIETY.**—On Monday, February 4, before the members of the Society, Mr. H. Snowden Ward gave his lecture on "Picture-making for Photographers." The lecturer commenced by showing the first efforts of the primitive symbolists who drew a vertical straight line as indicative of strength and vitality, and the horizontal straight line as indicative of submission and calm. In combining the two the triangle was formed, a symbol of stability and aspiration. The circle and oval afterwards drawn indicated by their curved lines feminine grace and beauty. From these, a picture built up entirely of straight lines or triangles gave a harsh effect, while one composed entirely of circles gave a weak, squashy effect. The combination of the two producing the most pleasing picture. Mr. Ward gave as his opinion that 90 per cent. of the pictures exhibited at photographic exhibitions showed the lack of the first principles of composition or arrangement of subject, and said that picture makers should think throughout the whole course of their work. The lecturer then showed by a series of diagrams the best way to build up or arrange a picture, showing the strong and the weak points in the position of the principal objects. Right-handed pictures, or those in which the eye is led from left to right,

are generally more satisfactory than those in which the reverse method is taken. Mr. Ward then made some remarks as to tone values. In a picture the highest lights should lead one to imagine that something lighter still could be shown, and in the deepest shadows that something even darker could be indicated absolute black or white should not appear in a picture.

We showed on the screen Mr. A. Marshall's Salon picture "Sunlight and Whitewash," which he considered the most perfect and masterly example of tone rendering he had seen exhibited for many years. If a satisfactory picture could not be made out of the materials at hand the photograph had better be left untaken. A few horizontal lines in an uninteresting foreground greatly improved the picture. In architectural subjects taken with a wide angle lens the foreground appears to run uphill, but a few horizontal shadows thrown across the same foreground will remove the uphill appearance, and these can generally be obtained by choosing the right line.

Pictures to represent spring or aspiration are best shown as upright panels, while those to represent autumn evening calm or tranquillity look best as horizontal panels. A picture which will not bear reduction or being hung above the eye indicated, in the lecturer's opinion, faulty composition. At the conclusion, a discussion took place as to the merits of certain of the pictures shown, but the lecturer said that he did not wish his statements to be taken as a rigid rule, but they were given as his own personal opinion and that candid criticism and discussion were always helpful. A hearty vote of thanks was then accorded Mr. Ward.

## Commercial & Legal Intelligence.

**CARRIERS' Liabilities as to Photographs.**—At the Manchester County Court, on January 21, Judge Parry heard an action brought by the Gainsborough Portrait and Enlargement Company, of Cheetam Hill, against the London and North-Western Railway Company, to recover £35 damages, alleged to have been caused by the delay of the railway company in delivering a number of enlarged photographs entrusted to them as carriers. The damages represented the value of 23 enlarged photographs at £1 1s. each, and four weeks' wages of a representative of the plaintiffs. According to Mr. W. E. Laycock, who appeared in support of the claim, the photographs were delivered to the railway company on August 10, to be carried from Manchester to Market Harborough. They were lost or mislaid until October 2. The result was that customers who had ordered the photographs refused to take them, and even complained to the police. The plaintiffs' representative was at Market Harborough four weeks waiting for the parcel to arrive. As a result of the non-arrival of these photographs his clients lost their connection in Market Harborough, and, more than that, the police were set on their track.

A representative of the firm said he waited at Market Harborough for the parcel for four weeks—till he was sick and tired of it. "The town was so small," he added, "that I got known to everybody, and the police got on my track." (Laughter.)

Mr. Frank L. Lambert (of Euston Station), who appeared for the railway company, pleaded the Carriers Act, 1830, contending that the photographs came within the definition of "pictures or paintings," in respect of which a declaration should be made and a higher rate paid. Many consignments of this type were being made at present, and the case was of some importance to railway companies. The goods miscarried by a pure accident. The adhesive label got rubbed off, and the parcel ultimately turned up at the lost property office at Euston.

The Judge: What about picture postcards? You might call them pictures or some of them waste paper.

Mr. Laycock argued that the photographs were of no value except to those who had ordered them. The "pictures" contemplated by the Act were pictures of value which might be stolen for their intrinsic worth.

In giving judgment, the Judge said the case raised a very interesting point. After fully considering the facts he could not honestly say that the photographs were "pictures" of value within the meaning of the Carriers Act, which was designed to protect carriers from serious claims for damages which they could not possibly foresee. The photographs might have a sentimental value to the individual who owned them, but they certainly had no commercial

value. He must therefore find for the plaintiffs, and he assessed the damages at £10 10s., with costs on the higher scale. It was certainly a case in which he thought the railway company should get the decision of a higher court, and he granted leave to appeal, with a stay of execution.

**"FAKED" Postcard Portraits.**—Last week, in the King's Bench Division, Mr. Justice Darling and a jury had before them an action by Mrs. Gertrude Monckton, the wife of Mr. Lionel Monckton, of Russell Square, to recover damages from Messrs. Dunn and Co., printers and publishers, in Barbican, in respect of alleged defamatory postcards published about her. The defendants admitted publication, but said the postcards were not defamatory.

Mr. Foote, K.C., for the plaintiff, said the defendants appeared to have got hold of a photograph of the plaintiff and had then "faked" a postcard by placing Mrs. Monckton's head on the body of some other lady, either by photographing or drawing. The photographs published of the plaintiff were libellous, and calculated to bring her into contempt.

The first picture of which the plaintiff complained was one in which her head had been placed on a body attired in a nightdress, and holding a candle in her hand, and any one looking at it would at once assume that the plaintiff had been photographed in that position. This gave her great pain.

In regard to this the defendants said the idea was taken from the costume of characters appearing in "A Night Out," recently performed at the Vaudeville. The plaintiff desired to put a stop to this, and asked the jury to read the defendants such a lesson that they would not repeat it.

Another photograph published by the defendants which was objected to was one which they said they took from the idea of "La Source." As a work of art no one could take objection to such a picture, but when the plaintiff's head was photographed so as to make anyone believe she was willing to be photographed in that position the matter became very serious and painful to her. There was a third picture which was vulgar, as it represented the plaintiff crawling out of an egg-shell.

The plaintiff, who was then called, said she did not think any one would like such photographs to be published of them because they were not pretty. (Laughter.) She had never been photographed in the positions indicated.

In cross-examination by Mr. Powell, K.C., Mrs. Monckton said that when she objected she understood the defendants did their best to get the postcards back, but they had no right to publish them. She was now playing a title-role in the "New Aladdin." As a man she had appeared in knee breeches and high boots, and had in male parts appeared as a costermonger and a Mexican cowboy, and in such costumes she had allowed her photographs to be published. The plaintiff further stated that she was not aware that Messrs. Garbett and Co. were the same people as Messrs. Dunn and Co. The publication of the postcards was first called to her attention by someone sending one to her and asking for her autograph. She then consulted Messrs. Foulsham and Banfield.

You know that Foulsham and Banfield's photographs are sold at 2d. each?—Yes.

And that those of Dunn's and others are sold at a penny?—I do not know that.

You did not write to Messrs. Dunn to object?—It was too late, the mischief was done, and apologies in these matters are no good.

Take the nightgown photograph, may I get your consent to think that it is a pretty photograph?—No, it is not. My reason for objecting is that the public would be under the impression that I was photographed in such a vulgar attitude, in my nightgown.

Do you suggest that no decent person would allow a picture of herself with a nightdress on?—I will not express an opinion; people have different ideas. I would not be so photographed.

Mr. Powell, for the defendants, asked the jury not to let their natural sympathy for a young, attractive lady lead them into wronging a mere tradesman who had not the charm of the plaintiff, and who was not before the public. They must keep in mind that it was an action for libel, and nothing else, and they had to ask themselves whether she had been defamed or not, or whether other people were likely to think less of her. There was a difference between those before the public and those who were not, and the latter might very well complain of that which the former could not. The district

visitor, whose greatest excitement was a mothers' meeting, might very well complain if, instead of her sombre garb, she were represented in some of the costumes which actresses sometimes wore on the stage, and were willing to be photographed in. The lady from the suburbs might very well feel defamed, because she might say, "I never could appear in public in that way;" but the plaintiff had appeared in positions which to some minds were more objectionable than the pictures in this case.

Mr. Ralph Dunn said that he had purchased over 600 photographs of actors and actresses; he had obtained the copyright to publish them, including one of Miss Millar. They had never published any without having paid for the right of doing so. He wanted a pretty picture of the plaintiff and other actresses, and having obtained from Germany the photograph of a girl in a nightdress, holding a candle, issued as an advertisement of the candle, he put the plaintiff's head on it. Thirty-four gross of the nightdress picture were printed, twenty-one gross of the egg-shell, and twenty-one gross of the stream picture, and twenty-two gross of the first, eight gross of the second, and eight gross of the third were sold. The wholesale price was a halfpenny, and the retail price a penny. He did not sell a single copy after complaint was made. He ordered about 10,000 of each.

Mr. Powell characterised the case as like the pictures. The figure-head was Miss Gertie Millar, but the heart and nerves and motive-power, and the whole force of the body was Mr. Foulsham and Mr. Cruesemann, the rivals in trade of the defendants. It was their interests that this matter was brought forward, to crush at trade competitors. If it were Foulsham's action, let them leave to him. He would never be so ungallant as to allow the plaintiff to bear the brunt of it. Counsel hoped the jury would say that it was an action that ought never to have been brought, and in the interests of fair play and justice their verdict should be for the defendants.

Mr. Foote declared that there was not the slightest warrant for the suggestion that the loss, if there were any loss, would not all on Miss Millar. There was something suggestive in the pictures, not too much, but just enough. He did not say they were decent, but there was just that about them which would make them sell.

In summing up, Mr. Justice Darling asked the jury whether they thought Mr. Sydney Buxton, the Postmaster-General, would take Mr. Foote's view of the stream picture. With regard to the one of the plaintiff coming out of the egg, nobody could suggest that there was anything improper in it. The only thing his lordship could see against it was that it was so common-place. The plaintiff was constantly before the public. She did not want to live absolutely unknown. It might well be that if a picture like "La Source" were published of the country vicar's wife she would have reason to be very annoyed. But it was not quite the same thing to publish photographs of a lady who was often exhibited in fancy costume, similarly with statesmen and private individuals. If any one put the head of one of the jurymen on one of the caricatures of Mr. Chamberlain and stuck them all round his place of business, he would have a perfect right to say: "Why should I be treated like this? I have not advocated anything for the good of anybody." (laughter.) They must not, therefore, forget the position the lady occupied, but at the same time they were entitled to draw a distinction between what represented the actress in a theatrical part and what represented her not in a theatrical part. They must look on it as plain common-sense men.

The jury gave a verdict for the defendants. Mrs. Monckton in a letter to the Press, states that she will not appeal from the decision, being satisfied with the verdict of the public.

**CHARGE Against a Photographer.**—At the Witham Sessions, last week, John Henry Rubens Bloomfield, alias Henry Rubens, travelling photographer, was charged on remand with obtaining 5s. by false pretences from John Oliver Turner at Rivenhall on December 1. Evidence showed that prisoner obtained from prosecutor an order for three photographs of Durwards Hall, and the photographs were to arrive on the following Tuesday. They never arrived, however, and prosecutor did not see the prisoner again until he had been arrested on January 21 at Brintree. The case was dismissed, as there was no legal evidence of false pretences; and prisoner afterwards handed photographs to the prosecutor.

## NEW COMPANIES.

**OTTO FULTON PROCESS, Limited.**—Capital, £30,000 in £1 shares. To adopt agreements (a) with F. Behm, relating to the allotment to him of 18,000 fully paid shares in consideration of services rendered in procuring certain British patents, stock, furniture, fixtures, fittings, and apparatus for this company, and (b) with the Fulton Syndicate, Limited, for the acquisition of certain British patents relating to photolinel, and certain stock, furniture, fixtures, and apparatus, and to carry on the business of photographers, engravers, decorators, artists, designers, publishers, printers, lithographers, picture dealers, film and photographic apparatus manufacturers, etc. No initial public issue. Registered without articles of association. Registered office: Worcester House, Walbrook, E.C.

## News and Notes.

**A SPANISH** contemporary solemnly prints, in a list of its staff of collaborators, *Mrs. A. and L. Lumière!*

**AN Optical Lecture Experiment.**—Mr. A. E. Smith, writing to "Nature," says:—A striking example showing how any large lens can "see" in relief may be demonstrated to an audience. An electric glow-lamp is lit in an optical lantern, and the image of the filament projected on to a screen. This image is only sharp in parts. A card with a small hole in it ( $\frac{1}{2}$  inch) is now placed close in front of the lens; this sharpens the image on the screen. The card should now be moved backwards and forwards; the image changes in a remarkable way with every movement, showing that the lens sees the filament from a different point of view from each point of its surface. Photographs taken with the "stop" at either side of the lens make a good stereoscopic pair.

**ANIMATED Photography at the Alhambra.**—On Monday last some new and brilliant films were introduced into the "Urbanora" exhibit. Miss Annette Kellermann, who has so nearly swum the Channel, was pictured in a delightful demonstration of high-diving; and in "Callers Herrin" the great fishing industry of Wick was convincingly illustrated.

**THE Photo-Secession.**—Next Tuesday a "two-man" exhibition in the "Little Galleries" of the Photo-Secession, New York, will close. The photographs have been from the cameras of Baron de Meyer and Mr. George H. Seeley.

**SUPPLIES of Platinum.**—Attempts are being made, according to the "Chemist and Druggist," to obtain platinum in the Yukon district. Although fine-grained platinum was recognised in the black-sand residue obtained along the Teslin or Hootalingua River, Yukon Territory, as early as 1898, until recently no active preparations have been made to recover it. A syndicate, whose concessions cover fifteen consecutive miles up the river from its mouth, are now preparing to exploit the river bed with a Risdon dredge, which will be equipped for saving the black-sand residues and extracting the platinum from them. Black sand from this river was treated by the United States Geological Survey's plant at the Portland Exhibition in 1905, the opinion being that the platinum, although exceedingly fine, is capable of recovery.

**ERRATUM.**—A correspondent calls our attention to an error in our issue of January 25 in reply to a correspondent asking for the length of side of a square enlargement to be twice that of one of its sides. The correct answer should have been  $\sqrt{162}$ —nearly 13in., not 4.2in., as stated through an arithmetical error.

**THE Catford and Forest Hill Photographic Society** are holding their Second Annual Exhibition at St. Mary's Hall, Ladywell, on March 22 and 23. There is an open class, and entry forms can be procured from the Hon. Sec., 169, Woolstone Road, Forest Hill. They must be returned by March 8. The judges are the Rev. F. C. Lambert, M.A., and Mr. A. Horsley Hinton.

**A CANVASSER'S BUSY DAY.**—Walter Witherington, a young fellow, described as a photographic canvasser, at the Accrington Police Court, was fined 5s. and costs, and ordered to pay £2, for a plate-glass window he had broken at the "Old House at Home" beer-house. Defendant stated that he stumbled on the step, and fell through the window. He appeared in Court with his hand bandaged.

## Correspondence.

- \*\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.**
- \*\* We do not undertake responsibility for the opinions expressed by our correspondents.**

### ADVERTISING.

To the Editors.

Gentlemen,—Messrs. John J. Griffin and Sons, Limited's, letter under this heading in your to-day's issue is incorrect.

There is no ground for the insinuation that we are attempting to pass off Ilford Portrait Gaslight Paper as Special Portrait Velox.

Page 16 of the "Velox Manual" quotes "Special Rough," "Special Carbon," "Regular Rough," "Regular Carbon," "Special Glossy," "Regular Glossy," "Velvet," and "Special Portrait," as varieties of Velox paper. Obviously these words are used in their general sense as ordinary adjectives.

The word "Portrait" means a likeness or representation of a person, and is properly applicable to any material designed for the purpose of portraiture. Witness Messrs. Marion and Company's and The Gem Dry Plate Company's "Portrait" Plates, 1895, and "Portrait" Lenses, dating from forty years ago.

We deny that Ilford Portrait Gaslight Paper imitates, or is intended to imitate Special Portrait Velox in any way.

We shall not trouble you with any further letter on this subject.—Yours faithfully,

Ilford, E., February 1, 1907.

ILFORD, LIMITED.

### PROPERTY IN ADJECTIVES.

To the Editors.

Gentlemen,—On November 26, 1897, Ilford, Limited, advertised a bromide paper in your columns as having a "rich velvety surface." Has the Ilford Company protested against the recent use of the word "Velvet" and "warned" the public that "Velvet" papers are not "velvety"?—Yours truly,

"ROSA DARTLE."

### PLATINUM RESIDUES.

To the Editors.

Gentlemen.—Your leader on platinum-residues in the current issue of the Journal is of considerable interest to me on account of my own experience in collecting these residues. Some time ago, I was using a considerable amount of platinum paper, and as I have always bestowed marked attention on the collection of residues, I made very careful provision for the collection and precipitation of the platinum residues. All developing baths, and the first acid bath, were collected in large earthenware jars capable of holding several gallons; when full the platinum was precipitated with iron protosulphate, and the supernatant liquid was not syphoned off until a test-tube examination showed that no platinum was present. A collection of what appeared to be black platinum was gradually accumulated at the bottom of the tank, and in a year's time this was carefully collected and evaporated to dryness. The result was about 4lbs. of dry precipitate, which, with 3lbs. of platinum ash, was sent to the refiners. The result, as far as any return to me, was practically nil. At the same time, I was getting from 60 per cent. to 70 per cent. of the prime cost of gold and silver back as value for residues. What was the reason for my failure with the platinum? I have consulted several experienced chemists, and they unhesitatingly confirmed my method of precipitation, as indeed do the text-books. The point of interest in your article to me is the fact that you recommend nascent hydrogen for precipitating the residue, and I am curious to know if this would have brought me a return for my trouble. Of course, a considerable portion of the precipitate would be oxalate, but there could be no doubt about the liquid being free from suspended platinum when it was drawn off. As I paid for platinum paper in the year I am referring to, close upon £90, the result is sufficiently discouraging. I have at the present time a good collection of platinum residue, but *cui bono*? It is not even potable!

I may add that the *bona fides* of the refiners is beyond question, and the failure must lie somewhere in my own methods of precipitation.—I am, Sir, Yours faithfully,

G. T. HARRIS.

Sidmouth.

[We can only say that our correspondents procedure appears quite correct, we shall be glad to hear from any reader who may have been able to locate the cause of a similar experience.—Eds. B.J.]

### CANINE PHOTOGRAPHY.

To the Editors.

Gentlemen,—I noticed your reply to "Grip" under "Canine Photography" in last week's "B.J." If "Grip" will supply himself with a crisp biscuit and nibble it just as he is going to expose he will probably succeed.—Yours faithfully, J. E. GUBBINS, Lieut.-Col. Westward Ho! R.S.O., N. Devon.

### "PHOTO-BUTTON" APPARATUS.

To the Editors.

Gentlemen,—I noticed a paragraph in your last week's issue stating that "photo-button" apparatus and parts are not made in England, but that I import them from abroad. Although I buy considerable amount of jewelry for this class of photography from America, I have been able to manufacture the dies, machines and button parts themselves here in London for the last three years, and I shall be glad if you would put a note to this effect in the JOURNAL.—Yours faithfully,

JONATHAN FALLOWFIELD.

146, Charing Cross Road, London, W.

[The British Photo-Button Company, Alton, Hants, also informs us they manufacture photo-buttons from material made in England.—Eds. B.J.]

### THE USE OF FLAMING SUNLIGHT ARCS IN PORTRAITURE.

To the Editors.

Gentlemen,—I was very interested in Mr. Gascoigne's courteous letter, more especially with reference to the relative cost of lighting, but I am afraid that he has misunderstood my previous letter upon this subject, for I did not, as he says, "state that there is more active red light than yellow light in the yellow flame carbons." What I did was to draw attention to the curious results of the sensitometer tests. I am afraid that I cannot do more than refer Mr. Gascoigne to my last letter.—Yours faithfully,

Gateshead.

ARTHUR PAYNE.

## Answers to Correspondents.

- \*\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.**
- \*\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.**
- \*\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, &c. Two unmounted copies of each photograph must be sent with the fee.**

### PHOTOGRAPHS REGISTERED:—

- A. E. Parkin, 53, King Edward Street, Hull. Photograph of Alderman Symons.
- J. R. Steadman, 41, Dudley Road, Sefton Park, Liverpool. Photograph of Baby Sitting in a Bath on a Chair in a Room.
- A. W. Sargent, 12, Albany Road, Cardiff. Photograph of the Lord Mayor, Cardiff. Mr. W. Crossman.

**SULPHIDE TONING.**—Can you tell me the reason why a large batch of bromide postcards, bleached with the usual ferricyanide and bromide formula, and toned with sulphide of soda, resolutely refused to tone? The sulphide was a freshly made up solution. The ferricyanide had been used two or three times, and my assistant informed me that it was rather slow in action. The loss entailed by a large batch of cards like this being lost is a serious item, considering the small profits on such cards, and if you can assist me I should esteem it a favour. Sample of the bleached cards are sent herewith.—DOLPHIN.

We are unable to assign any reason. We have heard of similar cases, but have not been able to indicate the cause or state a remedy. We should like to have more particulars of the prints—viz., developer, if alumined or not, etc.

**WEEDEE.**—1. We think there would be no objection to the plan you suggest. 2. Blue.

**J. V. T.**—There is very little advantage in a screen unless it employ considerably longer exposures. As your studio is so short we should advise you to select a lens of  $f/6$  aperture. With the larger apertures the focus will be too long if you are

secure proper covering power. You can see within what limits you must choose from the table on page 1128 of the ALMANAC.

**FLASHLIGHT.**—1. There is no patent in it. The effect can be got by double printing from two negatives, or with a repeating back. Write to Messrs. Jonathan Fallowfield, 146, Charing Cross Road. 2. You had better get "Magnesium Light Photography," by F. J. Mortimer (Dawbarn and Ward, ls.). Impossible to answer usefully in this column.

**BOOK REQUIRED.**—Will you kindly inform me through your columns where I can get a good book on trimming, mounting, and framing prints?—RICHARD B. SHARPE.

"Trimming, Mounting, and Framing" (Dawbarn and Ward, 6d.).

**RESTORING FADED PRINTS.**—I hope you will kindly give me reference to an article in your journal on a special book which treats of restoring faded prints on albumen or gelatino-chloride papers, if only for a short time for copying, etc. I have tried various methods, and yet could not come to satisfaction.—Hari Raoji Chandarikar.

There is no really satisfactory method by which faded paper prints can be restored. If the faded picture be put into a solution of bichloride of mercury—say, one part of a saturated solution diluted with two parts of water—the yellowness of the paper will be removed and the print generally made brighter and more suitable for copying. But no detail that has actually faded out will be restored. Prints so treated, if thoroughly washed, will last for many years without further change.

**REVERSED NEGATIVES.**—1. Where shall I find the best instructions for making reversed negatives? 2. Can carbon be made to equal a matt P.O.P. for rendering detail in the shadows of small negatives?—Toxo.

1. There are several methods of making reversed negatives which have frequently been described in these pages. However, here is a simple method: First harden the film of the negative to be reversed in a solution of formaline, or in one of chrome alum; wash and dry. Next soak it in a solution of carbonate of soda for, say, ten minutes, slightly rinse, and put the plate in water (10oz.), mixed with ½oz. of hydrochloric acid, and in a few minutes the film will leave the plate, and can then be transferred to another in the reversed position. Another simple way of producing reversed negatives is to take them direct in the camera by exposing them through the glass. In this case, it goes without saying that the back of the plate must be thoroughly cleaned before it is put into the slide. 2. Yes, certainly it can.

**W. J. C.**—Unless direct fraud can be proved against the canvassers, there is no legal remedy. The business is conducted on slightly different lines from that of Tanquerly, but both classes of persons are clever enough to keep out of the hands of the police.

**POSTCARDS, ETC.**—1. Kindly inform me if you know how the postcard publishers get at the shops to sell their cards? Is it done through wholesale houses such as sell the ordinary papers? Is there any way of getting a list of same for the various towns, as I feel confident it would not pay them to work the small shops in each town? 2. If we add acetic acid, alum and sulphite of soda in fixing bath to stop blistering, has it any effect in stopping the after-toning with the ferricyanide bath? Also, if we put them (the prints) in salt and water before fixing with the bath, as I have quoted, and then straight into the fixing, do these various things interfere with the permanency of the prints, or do you suggest a better remedy to harden cards and to stop blistering for those to be enamelled? 3. What is the best to spot cards with glossy bromide previous to being enamelled? We have tried water-colour with albumen, but all comes off when prints are wetted.—ACETIC.

1. Stationers are travelled by the large postcard houses and by the wholesale firms dealing in stationers' supplies. There is no list. The wholesale newsgagents, we believe, do not touch postcards as a rule. We should advise you to consult a stationery journal such as "Morris's Trade Journal." 2. Our own attempts to cause such a bath to prevent the after-toning have failed, but we have heard of cases where the use of an alum fixing bath seemed a possible explanation of difficulties in after-toning. We cannot say precisely. The salt is usually removed before fixing, but it is not absolutely necessary to do so. If

left in, the prints as they go to the alum-fixer, it will not affect the permanency. 3. Special glossy spotting colours are sold by Fallowfield.

**PURPLE-BROWN TONES.**—Will you please inform me how I can obtain a purple-brown tone upon bromide and gaslight postcards. I have tried several modifications of the sulphide toning, and also the hypo-alum process, but with these I can only get various 'sepia' tones. The exact colour I want is that of the toned bromide postcards issued by the Rotary Company.—SEMPER IDEM.

If you employ the Rotary papers you should have no difficulty in obtaining the precise tone for which the hypo-alum process is recommended by the makers. The following method of preparing the bath is recommended:—

Hypo .....	50 gms.
Hot distilled water .....	300 ccs.
Alum .....	5 gms.
10 per cent. silver nitrate solution...	1½ to 2 ccs.

This last constituent is only needed when making up fresh bath. Heat the fresh bath two or three times to 122 deg. to 140 deg. Fahr., allowing it to cool after last application of heat. The solution should be used at 100 deg. to 120 deg. Fahr.

**W. S. T.**—We are not aware of such positions occurring frequently, but when they do they are usually advertised or filled by the firm's fitting up the party.

**MAGNESIUM LIGHT.**—Can you please tell me of any method of using magnesium ribbon in a room for illuminating a subject without producing the peculiar smell connected with the combustion of this article?—H. J. L.

The Platinotype Co. supply a lamp in which the magnesium is burnt in a closed chamber. The alternative is to construct framework covered with muslin (impregnated to diminish its flammability) in which to burn the ribbon.

**S. E.**—We think you cannot do more. We should say an entry of, say, a dozen subjects would be acceptable and stand a good chance of exhibition. We should not advise you to send more, and you had better keep a list of the subjects in order that you may send rough prints to identify them. Some of the Continental exhibitions find it difficult to deal with English work.

**PHOTOGRAPHIC DEALING.**—I am serving my time as a photographer, and I want to take up photographic dealing, chemist, etc., when finished my apprenticeship. Are there any books that would be of any help for same? Are there any classes I could attend?—H. S. B.

There are none of either. Your best means of getting experience is to take a position as assistant at a dealer's.

**A FRENCH LABEL.**—In taking stock, I find a bottle labelled "Phosphate tribasique de soude," which I take to be a sodium phosphate. Please say how or what way this is used in photography, also exact English translation.—A. CLARKE.

Tri-basic phosphate of soda used as an alkali in developers and placed on the market by the Lumière N. A. Co.

**TITLE LETTERS FOR NEGATIVES.**—You advertised recently in THE BRITISH JOURNAL OF PHOTOGRAPHY a firm who sell loose letters for sticking on negatives for the purpose of naming them. I should esteem it a favour if you would kindly give me the name and address of the firm.—FREDK. SUMNER.

O. Sichel and Co., 52, Bunhill Row, E.C.

**CARBON PRINTING BY ARTIFICIAL LIGHT.**—(1) Can the oxygen and coal-gas limelight be satisfactorily used for carbon printing? (2) If so, how does it compare for intensity, etc., with the electric arc light? (3) Is the electric arc light considered a complete success for carbon printing? (4) Is any other light available for the purpose?—HANOVERIAN.

(1) It could be, but the exposure would be very long. (2) The limelight would be very much slower; but no comparison can be given, as that must, of course, depend upon the power of the two lights. (3) Yes; but it is somewhat costly to use, and for that reason is but little used by professionals, except in cases of urgency. (4) The mercury-vapour lamp is good for the purpose, and is, we know, employed by one firm when daylight is not available and orders have to be executed. This light requires a continuous current.

**CELLULOID SQUEEGEERING ON GELATINE PRINTS.**—Can you enlighten me as to the proper method of squeegeeing coloured (by dyes) photographs in contact with celluloid, so that they remain so permanently? We have tried soaking in spirit, also water, then squeegeeing bubbles out, and putting under warm iron, but when the photograph is dry the celluloid peels off.—E.

The prints are dropped in spirit and attached to the celluloid by hot pressure. Messrs. Fallowfield supply a roller for the purpose.

**LIEUT.-COL. J. E. G.**—Many thanks for your correction.

**OPERATOR.**—(1) At such high speed a very fast plate—also one that is a very good plate—is necessary. We advise you to try one of the ultra-rapid plates sold at prices in advance of the "popular" prices. (2) If you will apply at the side door of the offices up to 6.30 you will be admitted on mentioning your name.

**FLASH.**—Certainly, you require a lens of much better covering power, one that at  $f/16$  will cover your 12 x 10 plate to the corners. You should get a lens of 7 or 8 inches focus, which will do this. If you look up the makers' lists with these requirements in your mind you will be able to judge of their respective merits. We should advise No. 5 of the W.A. series you name in preference to No. 4, or to the No. 5 of the other series.

**UNTONE PRINTS.**—Are prints that are only fixed in hypo as permanent as those that have been toned with either platinum or gold, previous to fixing? I am of the opinion that they are not.—A. GREGG.

On theoretical grounds and in practical experience they are not.

**HAND CAMERA.**—I am wanting to buy a hand camera, and should like your advice as to choosing. Is it possible to take just ordinary snapshots and microscopical objects, with the same camera, or is it a matter of different lenses? I am not wanting an expensive one (about £2 would do), and should be much obliged if you would let me know what kind to get.—D. WHITE.

Your requirements are totally antagonistic. For direct enlarged work you require a very short focus lens and a great extension of camera. There is no instrument which can be recommended to you. The best thing you can do is to study an elementary text-book of the two subjects. See the list of books in the "Almanac."

**LANTERN SLIDES.**—(1) Can you tell me if there is any book on lantern slide painting, or where I can get colours for same, other than oil? I have been using dyes (Judson's), and although I get nice soft coloured slides, when enlarged to any size the colours hardly appear definite enough. (2) Can you tell me what colours are used for commercial slides? (3) I have been told that the most transparent colours are albumen. Are they used in the same way as water-colours? (4) Do you think 2s. too much for making a slide from a print? My customer thinks so. He also thinks 9s. per dozen for slides by contact, and 12s. for slides by reduction, exorbitant. What do you think? I feel inclined to tell him to take his work elsewhere.—SARNIA.

(1) "The Book of the Lantern," by T. C. Hepworth, at 3s. 6d. (2) Oil colours. (3) Transparent tinting colours for lantern work are supplied by Fallowfield, and are used as water colours. (4) Both are reasonable prices.

**TINTING ENLARGEMENTS.**—(1) What water-colours or photo tints are suitable for tinting enlargements on semi-glossy paper, so as not to show smeary work when dry, chiefly to be permanent and transparent? I have tried some colours, which are all right, but sink into paper sometimes, and sometimes not, making it awkward to judge how much colour to apply, and chiefly they fade in a few days on exposure to sun, so are useless. After colour has sunk into paper, print looks like a faded coloured print, but on looking through it the colouring is quite strong. (2) What would prevent these colours sinking in?—NELSON.

(1) If you wish to colour the photographs in washes (i.e., without stippling) the only really successful method is to use aniline colours or dyes, but unfortunately none of these are permanent. Many of the better class of water-colours are fairly permanent, as may be seen from Messrs. Reeves and Sons' list, but some stippling with these is necessary. (2) To get over the difficulty of the colours "sinking in," either brush the prints

over or else immerse them in celluloid varnish, and when dry, again in a weak gelatine solution. This will give you a gelatine film to work upon, without the possibility of the colour getting to the paper surface below.

**H. MOORE.**—Try a set of three—namely (1), aqueous solution of gamboge for yellow; (2), aqueous solution of indigo with oxalic acid for blue; and (3), solution of dragon's blood in methylated spirit for red, the latter being invariably applied first.

**G. C. H. W.**—Our experience of the suggested apparatus has not been regular, but our recommendation is emphatically in favour of the dark slides.

**A POSTCARD DISPUTE.**—Some short time ago I took a photograph of a railway accident near here. The following day I had a person call on me, wishing to know if I would sell the negatives (two) or two prints. I was assured that if I sold two prints to him it should in no way interfere with the sale of my own postcards, that they would keep them to their own district. After a little talking and consideration, and thinking that they were twenty miles away from me, I consented, and sold him two prints for 7s. 6d., and to receive one gross of postcards from them free of charge. Now, after about a week from selling the prints, I find they are selling their cards to a stationer here, and extensively advertising them. I have written to them denouncing their principle, and asking them to withdraw the cards in circulation here at once. To this they have not replied, neither have the cards been withdrawn. I may also add that they have registered the prints, and they print their name and copyright on each card. What is my remedy for such a mean action, and have they any right to copyright the prints without my permission, as the negatives are mine and in my possession?—S. P.

You have conducted the transaction in a very unbusinesslike way, but from your account it was evidently your intention to grant the parties right to reproduce, though you must surely know that the purchase of prints transferred no rights. Legally the parties have infringed your copyright, but you cannot take action for publication before registration by you of the photograph. We assume you have not registered the photograph. You had better do so at once, and you can then stop further sales. The infringers have no right to register in their own names. We advise you not to take a dispute, arising from your own ignorance of copyright, into Court.

**STAGE PHOTOGRAPHY.**—(1) If a person pays for a seat or a box at a theatre or music-hall, would he lay himself open to action or penalty (a) if he photographed a stage setting, or (b) any particular performer during the course of the usual evening performance? (2) Would he be at liberty to use such photographs for picture postcards or in other manner, after copyrighting them, always, of course, providing he did not use them in any objectionable way?—H. G. W.

(1) (a) and (b) We believe the managers of a theatre have absolute rights as to permitting or restricting photography, whether such photography interferes with the audience or not, but we doubt if legal action could be taken afterwards in regard to photographing in the theatre. (2) Once the photographs have been obtained, the photographer could do as he liked with them.

**\* \* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The exhibition of photographs by American professionals at the J. offices closes to-morrow week (February 23).

Mr. J. C. S. Mummery has been officially (and enthusiastically) elected president of the Royal Photographic Society. (P. 120.)

Mr. Chapman Jones, in a letter to the B.J., states his attitude towards the R.P.S. (P. 128.)

The Photographic Convention has been invited to Brussels for 08. (P. 115.)

Demonstrations to photographers by acknowledged leaders in the profession (in the leaders' own studios) is the latest activity of the Professional Photographers' Society (New York). (P. 113.)

The increased imports of British dry plates into Germany last year—nearly nine times that of 1903—is causing uneasy apprehensions in the Fatherland. (P. 114.)

A case in which a photographer was alleged to have libelled a sister by exhibiting a portrait of him was decided last week against the photographer. (Pp. 114 and 124.)

The concluding chapter on aerograph work deals with finishing water-colour. (P. 115.)

Dr. W. Scheffer, of Berlin, publishes the results of photomicroscopic researches on the grain in gelatine plates. (P. 116.)

Patents of the week include reflex and stereoscopic cameras and picture postcard. (P. 121.)

The South Suburban Photographic Society is the title of the new society with its headquarters at Lewisham Junction. (P. 125.)

Lantern slide making, as demonstrated at the L. and P. by Mr. S. Teape, is reported on page 126.

## EX CATHEDRA.

### A Possible Convention in Brussels.

We are informed that the President of the "Association Belge" has forwarded a cordial communication to the "Photographic Convention of the United Kingdom," inviting the members to hold their next year's meeting in Brussels. Among the interesting and attractive places to which excursions might be made are mentioned Bruges, Ostend, Ghent, Antwerp, Malines, Villers la Ville, Dinant, and the wonderful Grottoes of Han. The "Association Belge" is a photographic body with its headquarters in Brussels and with numerous societies in other centres with which it is in very close relations. In fact, the Association is fully representative of photographers in Belgium in a more direct way, for example, than the Royal Photographic Society is of those in Great Britain. A meeting in Belgium would be a welcome change in the Convention's itinerary, and one which, we have no doubt, a large proportion of the members would favour. The Council will consider the proposition between now and the Hereford meeting, on which occasion the place of the 1908 visit will be fixed.

\* \* \*

### A New Move by the American "P.P.A."

The Professional Photographers' Society of New York, a body with aims almost identical with those of the Professional Photographers' Association in this country, has hit upon a new form of activity which should attract many new recruits into its ranks. It has arranged a series of five demonstrations, by leading professional photographers, of special branches of the profession, to which each one of the demonstrators has devoted years of his life, and in which he has obtained universal acknowledgment of his ability. The first subject will be child photography, to be demonstrated in his own studio by Mr. E. B. Core, of New York. Mr. Core's business, as our readers may have learnt from our columns, is confined exclusively to children, and the examples of his work which are now to be seen in the little exhibition at our offices have shown the peculiar strength and delicacy of his portraits. He has his own methods, and these he will demonstrate to a party of twenty of his fellow members of the Professional Photographers' Society. This is a form of service which is bound to be of the greatest value to men who are struggling from the lower ranks of the profession, and it is one which, with some differences, necessitated by the smaller distances which separate photographers in this country, might be carried out by members of the P.P.A.

\* \* \*

### Certification Mockery.

A bold man is Mr. E. J. Mock, of Rochester, U.S.A. We read in the "Photographer" that he has proposed a scheme of certification for photographers which certainly has the merit of being unlike anything of the kind of which we have ever heard. Yet we are not in two minds of the possibility

of carrying it through in any general way. Mr. Mock suggests that one or two photographers and one or two artists in a town band themselves into a committee to grant certificates of proficiency to photographers in the district, on the basis of work which is genuinely their own from first to last. The certificate is to be for a single year, and at the end of that time may be renewed if the output of the photographer merits its continuance. We should like to see the idea suggested in any town in Great Britain! Mr. Mock argues that photographers who know their business from end to end should have a diploma no less than dentists, but he also seems to take the view that a self-awarded certificate is just as valuable as one granted by a public or national body. Perhaps it is—in America.

#### A Photographer's Libel

The sequel to as silly an act as any portrait photographer can perpetrate is reported in our "Commercial and Legal" column this week. It took the form of an action for libel brought against a photographer in Bishops Stortford by a person whose portrait he had taken in the usual way of business. Failing to obtain payment for the photographs the photographer displayed one in his window above an insulting reference to the person represented. The latter, in an action heard at the Hertford Assizes on Saturday last, obtained a favourable judgment and one farthing damages, the costs of the case, of course, falling upon the foolish photographer. Our readers may recollect our commenting on the incident at the time of its occurrence, and that we ascertained the calling previously followed by this "professional photographer." It is when silliness of this kind is reported in the newspapers that one wishes it were possible to exclude the ex-sweep, and cook, and candlestick-maker from posing to the public as a professional photographer.

#### Sunlight Arcs.

Our recent article on sunlight arcs for portrait work has aroused considerable interest, and we have had a good deal of correspondence from users of electric light. It is, we believe, fairly correct to assume that with the same cost for electric energy something like three times the illuminating efficiency is obtained with sunlight arcs as against ordinary arcs, the measurement being made with such an instrument as the flicker photometer. But it must be borne in mind that such a comparison does not hold with lamps of the enclosed type for photographic work where the adjustments are specially arranged to give a light of great photographic efficiency, owing to the preponderance of the violet and ultra violet rays, which possess very little illuminating power. In estimating the relative cost of various lamps the question of carbon consumption is one that cannot be ignored. The consumption of carbons in flame arc lamps may be taken as being approximately three times as great as in enclosed-type arcs. The vapour of silicates and fluorides increases the conductivity of the arc, a longer arc resulting. Not only is the actual consumption heavier, but the cost of the carbon is greater to begin with. Reference has been made by a correspondent to the variable quality of the light obtained when using soft-cored carbons. Where the substances introduced to give a colour to the arc are used as a true core, this is no doubt the case, the soft core being consumed a certain distance down into the carbon, when for a time the substance of the carbon is alone incandescent, this continuing until the core is again reached. When the sodium, calcium, strontium and other salt is incorporated with the carbon this variation is hardly likely to occur to any appreciable or measurable extent, and, at all events, would have no effect in practical everyday portrait work.

#### BRITISH PLATES IN GERMANY.

Photographic Plates imported into Germany from Great Britain (kilos):—					
1903.	1904.	1905.	1906.		
9,800	25,300	38,700	89,000	...	...

MANUFACTURERS of photographic plates in this country should read with satisfaction the outcry against the increasing imports of English plates into Germany which recently been made in that country. It has, we think, been generally acknowledged that in the production of gelatine plates of extreme rapidity and other good qualities Great Britain has never had a rival, a pre-eminence which after all, is a natural corollary of the invention and perfection of gelatine emulsion processes in these islands. The result has been that in open markets the British dry plate has held its own against all comers, and has now shown its capability of disturbing the ranks of manufacturers in a country where home production is favoured and foreign competition handicapped by a tariff.

It is not so many years ago that the plates introduced into Germany did not amount in all to a total of any importance, but the keen competition between British makers has doubtless been the cause of the attack on every available market. The commencement of the appeal to the German consumer may be said to have been the indirect result of the introduction of the "popular" prices for plates some years ago, a step which was taken by the Ilford Company, and with which practically every plate maker has fallen into line. Before that time the home prices of English and German plates were so nearly alike that on this ground there was not the opportunity for a satisfactory competition, but whilst the reduction of prices in England was adopted almost without an exception, in Germany it was adopted at first by only one or two firms. As a result, so we are told by our contemporary, "Die Photographische Industrie," the impression was made that the cheaper plates were inferior, in which view the consumer was encouraged by his dealer.

The next phase in the German dry plate trade was a keen competition among the makers by means of increased discounts, as a result of which an effort was made a few years ago to establish a uniform minimum price. It failed to achieve its object; on the contrary, several makers further reduced their prices and raised their discounts.

It is within the last two or three years that the increase in the imports of British plates has become of notable proportions, and in the last year has risen to a total which is described by our contemporary as "gefährlich für die deutsche Industrie." Our contemporary, which, though lately established, may be said to express the views of the German photographic trade, urges the German makers to take a more serious view of this competition, and to take such steps as shall place the makers in a position to compete effectually with the English importations. In reference to the first of the two factors in the case, quality and price, the German writer takes the comfortable view that the German plate, coming as it does from a nation of the scientific attainments of Germany, must, of necessity, be better, an assumption which we should imagine may be rudely dispelled at any moment by a short conversation with an emulsion maker. In regard to price, the German, despite, or rather, in consequence of, his tariff laws, is not at the advantage which will enable him to produce a high grade plate at a price considerably below that of the English article; for he has to import his glass from Belgium or Great Britain, and to pay on it pretty nearly as much duty as paid by the importer of the English plates. Therefore the cry is raised of German-made glass for the German plate-maker, a scheme which very possibly Germany may realise in time, though she has a formidable task before her in establishing factories with the facilities

of the Belgian glass works, even when she has overcome the technical difficulties. Indeed, it will be remembered that the Germans had every incentive to perfect the manufacture of glass for dry plates six years ago, when the duty on glass from Belgium and Great Britain was increased forty per cent.

In addition to these two limits to the expansion of the home production of the German plate, there is, according to a correspondent of the "Photographische Industrie," another which is self-imposed. The writer states that many German plate factories have carried on their trade in Prussia, Bavaria, Saxony, Wurtemberg, and Baden, by establishing a sole agent from whom the dealer in these States of the German Empire must purchase if he wants the plates. Usually he will not do so for the two reasons that the agent is a direct competitor with him, and that in dealing with him he does not get the full discount obtainable from the manufacturer direct. If plates were supplied by the maker direct at full discount in all parts of Germany, it is thought that the dealers in these States who are now purchasing British plates would discard them for those of home manufacture.

Those who have moved in German photographic circles will recognise in this appeal to the German makers to be up and doing the tacit admission of the superiority of the

British manufactures. And it is a fact that in the case of many products, the name of an English maker is a guarantee of quality. We remember paying a visit some years ago to a large German polytechnic, in the instruction rooms of which we found students being shown the making of positive transparencies on Thomas's plates, and of carbon prints on "Autotype" tissue, and in more recent contact with the German professional photographers it has been our gratification to observe the favour extended to manufactures in the way of plates and printing papers which are "Englische fabrikat." Therefore it is all to the good of the English maker that he has a reputation to live up to ready-made for him in Germany, and he needs only the commercial enterprise to push his goods among the consumers in that country. In doing so it may be well if he keeps in mind the few special preferences of the German photographers, chief among which is the lesser use of pyrogalllic acid as a developer than in this country, and the greater favour which is given to the more recent reagents such as amidol and rodinal. Stand development, on the other hand, is much more greatly in favour with the German amateur photographer than is the case with his prototype in this country, and the reigning system of signifying the speed of plates is, of course, that of Scheiner, a modification of the Hurter and Driffield method.

## WORKING - UP AND COLOURING WITH THE AEROGRAPH.

The article printed below concludes the series of chapters on this subject which has recently appeared in our pages. The previous contributions have dealt with the elementary practice necessary to obtain proficiency in the use of the instrument and with the methods to be followed in undertaking commercial work of this kind.

Coming to the subject of finishing in water colour, the writer is of opinion that it is desirable, especially for beginners, to confine themselves to as small a number of colours as possible, and to work the tints as pure as possible—that is, not mix the colours each before applying them. This would perhaps sound like impossible advice to a worker with a brush, but it is not only thoroughly practical, but desirable, in working with the "aerograph," for the reason that you can modify any tint on your picture after it has been applied in such a delicate and almost imperceptible degree that the trouble of mixing tints may be avoided.

You have the double advantage that you can study the colours, *situ*, and not as a liquid on the point of a brush or on a palette, and the "aerograph," instead of concealing the place where you are working, as a brush would do, permits you to develop the tint as a photographer develops his negative, but with more freedom. An "aerograph" will distribute tints of colour so delicately that on a white paper you could go over the surface several times before the tint is visible.

### The Colours to Start With.

For a beginner's palette we should recommend the following colours, which are placed in two groups, those under A being permanent, and those under B being nearly permanent:—(A) Venetian red, light red, Indian red, raw and burnt sienna, raw and burnt umber, cobalt blue, lamp-black. (B) Vermilion, carmine, sepia, Prussian blue, Indian yellow, lemon yellow, Hooker's green No. 2, vandyke brown, Chinese white.

It is desirable to have two glasses or cups of water, one in which to clean brushes and clean your "aerograph," and the other with which to prepare fresh colours. It is not possible in the limits of articles to give a very comprehensive system of colouring. The subjects vary so materially, and there is so much

to be said which is difficult to put into language that all we shall hope to do is to give a rough outline and indicate the points wherein the "aerograph" treatment would vary from the ordinary work with brushes.

We find it desirable to rough in a little colour to show the colour-scheme. If you have bright-coloured drapery, for instance, or hair which is to be brightly coloured, it may affect the work upon the face, unless a little portion of the colour is put in; it need not be finished.

### Flesh Tints.

In colouring the flesh, the first treatment will be to make a thin wash of a light yellow red. This red would vary in character somewhat for different subjects, and also to meet the conditions of the print. If you have a portrait of a child where a fair delicate complexion is wanted, and your print is very dark, you have but one resource, and that is to put over a thin wash of scarlet vermilion. In the case of an older person, where so much delicacy and colour is not required, it is more desirable to make this first flesh wash of Venetian red or light red. These may be modified with vermilion to treat an especially dark picture.

Try to go over the flesh pretty evenly with this tint, shadows, high-lights and all, being careful not to get too much on the forehead or other very light parts—not sufficient to make them appear red.

The next step will perhaps be to strengthen or colour the deeper shades of the face: Indian red, or Indian red with a little burnt umber, is a suitable colour for this work. Put the lines of the eyelids, the shadows of the ears, the upper lip and a portion of the lower lip, the nostrils, and the heavier shadows on the cheek and neck, with this dark red colour. A considerable quantity may be used on the lips and on the ear, and about the

wings of the nostrils; a little touch also under the lower lid of the eye, and, if the colour of the cheek is in shadow, a considerable amount of this colour may be used on the cheek, and perhaps a little on the chin as well.

### Colours for the Hair.

It will perhaps be as well at this stage to colour the hair, or some portion of it, and get in more of the various colours in the drapery, which are likely to modify your work by contrast. It will also relieve your eye of the flesh colour, so that when you go back to it you approach the subject with an eye less fatigued. The shadows of the hair should be warm in golden or yellow hair; the yellow tones appear for the most part in the half-tones between the dark and the extreme light. Little touches of blue and green may be put in in finishing the hair, but they must be done with great care, and never put into the shadow or darkest parts. It will perhaps be best now to return to the flesh colour. Examine it with a view to see where the photograph shows itself through the colouring, and try to get rid of this photographic or bluey-black effect. Raw sienna and sepia are both useful colours to use in suppressing this photographic effect. Your flesh colour will now be of a warm tone throughout, and you require a few touches of grey. If you were painting with brushes you would be compelled to prepare a suitable grey, and stipple, or wash it locally. The "aerograph," however, will distribute tints of colour so delicately that you may take, say, crude Prussian blue, and soften the flesh colour where it meets the hair; little touches of this blue may be put in to represent the veins of the forehead if the subject is thin-skinned. A little blue colour may be used at the side of the nose near the inner point of the eye; a little just under the eye, a very little upon the upper lip and at the outer corners of the eye, and upon the neck. These blue-grey tones, bear in mind, come between the shadows and the extreme high-lights. For the most part the shadows should be warm, and the high-lights have a tendency to yellow. Touches of green may be used in place of the blue; a little of this colour, about the temples and outer corners of the eye-sockets, and along the edge of the hair, will give an appearance of flesh colour. A great deal of green colour may be used in the face of the brunette

type. The colour in the cheeks for the children may be a combination of alizarine and vermilion, keeping the vermilion near the high-light. This should be put in a more or less triangular shape, on the bones of the cheek, and just a little on the point of the chin; but it should not be put on too smooth, as if rouge had been used. The colours in nature are slightly mottled and spotty.

The lower lip may have a touch of this bright colour, and a very little may be used about the wings of the nose and under the lower eyelid, and a considerable quantity in the ear, which is almost invariably a pinky colour. The eye must be painted to suit the subject; the iris is the part to receive the local colour; the pupil must be very dark, except in the case of a very pronounced blonde; the eyelashes and shadow of the upper lid will be represented by brown colour, light or dark, to suit the subject. A little bright colour may be put in the inner corner of the eye.

### Backgrounds.

Coming now to the background, colours should be employed which carry out the colour-scheme of the picture, but it must always be remembered that to produce the atmospheric effect about the head, the colder colours must be employed for the portion which will represent the distance—that is, the upper part of the background; the lower part, in practically every case, representing the foreground, may have some warm colours with some drawing of detail in them. There is much scope for the artistic taste of the painter in doing the background. As before recapitulated, for black and white work it is desirable that the different tints should represent planes, so to speak, of shadow or colour in the background—not sharply or definitely defined, but still planes of colour blending the one into the other. There are many books which treat of the colouring of details of drapery, and the like, with a brush, which do not vary considerably from the rules for "aerograph" work.

Lastly, do not work on the picture mechanically without thought. When you are not doing a picture good you are almost certainly doing it harm. Think about your work, and if you find that you fall into the habit of working mechanically, correct yourself in every possible way.

## MICROSCOPICAL RESEARCHES ON THE SIZE AND DISTRIBUTION OF THE PLATE GRAINS.

To examine the change of size which the grain undergoes in development, different compounds of the halogen salts of silver were developed in test tubes and the photo-micrographs of the undeveloped and developed grain were compared. Fig. 1 shows silver bromide formed in water (Stas. flocky yellow form). It is seen that the single grains are united into groups. The upper superfluous fluid has been poured from the yellow masses and these have been washed in different changes of distilled water. The grains were developed in a five per cent. rodinal solution. Fig. 2 shows the grains after development. Fig. 3 is crystallised bromide of silver. Fig. 4 shows what these crystals have become by development. In both cases the developed grain has quite a different form from the undeveloped. The two developed grains (figs. 2 and 4) are very similar, although they are the result of the development of quite different halides of silver. A comparison of the size of the developed and undeveloped grain shows that in fig. 1 and fig. 2 the grain formed by development is much larger than the undeveloped.

In figs. 3 and 4 the difference of size between the crystal and the black grain is smaller. There is no noticeable difference between the developed grain, figs. 2 and 4. We call a developed grain a more or less distinct mass which is connected with the neighbouring grains by small bridges. Naturally, the experiments have been carried out so that in every development equal quantities of silver have been developed in equal quantities of developing solution. The different stages of development have been examined in very thinly-coated emulsions of silver bromide. Fig. 5 is undeveloped. Fig. 6 shows the first stages of development. Jutting out from the grains are shorter or longer filaments which are either straight or irregularly curved and mostly terminating in a knob. These filaments have also some times thickenings in their length besides the terminal knobs.

Fig. 6 is a part of the preparation which is especially rich in such germs in the first stage of development. Naturally, these filaments are stretched out in all directions of space. In the photo-micrographs only those situated in the focal plane are sharp; the others, whether through the grain or cover it partly, and seem to be more or less opaque bodies which sometimes seem to divide the grain into compartments. An examination of a grain

NOTE.—On the photo-micrographs the magnification of the originals from which the half-tones are taken is 800 diameters, except figs. 5 to 7, which are 2,150, and figs. 5a to 7a which are 4,000. The reduction in making the half-tones was to about  $\frac{1}{5}$  scale in the figs. 5 to 11: nearly full scale in figs. 12 to 19.

number of preparations shows that the smaller grains have comparatively more of these filaments than the larger ones, if we

results of something similar to an explosion which takes place during the exposure. Small bodies are shot away from the

take the relative masses into consideration. It gives me a strong impression that the formations described here are the grains and they make their way through the gelatine either in straight or in irregularly curved lines. The filaments are

formed by parts of the small bodies shot off which remain in the path. Sometimes at the end of the path the small particles can be seen as a terminal knob. In other cases the whole is used up on the way. Both the terminal bodies and the filaments are the germs at which development commences. Sometimes

formation of the developed grain commences are situated outside the original grains, and that also the further stages of development take place outside the original grain. This can easily be seen, as long as the original grain is not entirely covered. These bodies can be seen only with very good oil

Fig. 15.—Long exposure.

Sections through films which have received different exposures.

the filament is hardly visible even with the highest power oil-immersions, but the small body, apart from the grain, and the grain itself are only connected by the trace of a shadow.

Fig. 7 shows a further stage of the development. The fine germs are changed into more or less clumsy bodies, which rest upon the original grains and have partly grown round these. At any rate these researches show that the germs at which the

immersions and with a fully open condenser. They behave like stained bodies—for example, stained microbes.

Figs. 8 to 11 show a very thin coating of silver bromide in gelatine. Fig. 8 is undeveloped. Fig. 9 is developed for one hour with one per cent. rodinal solution. Fig. 10, the same with a ten per cent. solution.

The grains obtained with the one per cent. solution are

partly considerably larger than the undeveloped grains, partly equal in size and some are smaller. The ten per cent. solution has produced larger grains than the one per cent. solution. There can be seen some original grains in fig. 9 upon which rest developed masses. Also in fig. 10 there are to be seen some original grains which are not quite covered. Upon these rest much larger developed grains. Figs. 8 and 9 show that

are rendered much fainter. By this they are somewhat less clear in the microscope, but by suitable illumination they can easily be made visible. Apparently, in this case, the bromide of silver dissolved in the developer is an obstacle to the dissolution of those grains which do not take part in the development. It is interesting that in fig. 11 the developed grains are much clumsier than in fig. 9 and 10. In preparations like fig. 6

Fig. 16.—Emulsion side exposed.

Fig. 17.—Glass side exposed.

Sections of films exposed from front and back respectively.

only a certain part of the grains becomes original grains for the development. The others are dissolved by the developer. Naturally, the plates 8 to 11 have not been fixed. For examining this more exactly some bromide of silver was dissolved in the developer and I developed with this solution.

Fig. 11 shows the result of this experiment. The grains which have not become original grains are not entirely dissolved, but

it can be clearly seen that only a part of the grains become original grains.

Also in preparations like fig. 6 some grains show no trace of having germs round them. The examination of a great number of preparations like fig. 11 shows that probably the number of original grains and the number of those which take no part in the development are about equal in sufficiently exposed plates.

Even if we expose very long it is not possible to make all grains original grains.

Figs. 12 and 13 are sections through a film in different stages of development. In fig. 12 the development has just commenced. In fig. 13 the film is fully developed. Naturally both parts are from the same plate and are equally exposed. In this experiment all the conditions for both parts were the same, and only the time of development was changed. It can be seen from figs. 12 and 13 that not only the size, but also the number in the unit space of the film and the topographical distribution of the grains in the same depend upon the time of development. Figs. 14 and 15 are results of an experiment in which only the time of exposure has been changed. Fig. 14 is a section through a shortly exposed plate, and fig. 15 of a longer exposed portion of the same plate. From these images it can be seen that the number in the unit space and the topographical distribution of the grains in the film depend upon the time of exposure. If a plate is exposed in such a way that by exactly the same exposure one half from the glass side and the other half from the emulsion side have received the same amount of light, and if this plate is developed, then, firstly, the half exposed from the emulsion side commences darkening, viewed from the emulsion side. After a short time also the half exposed from the glass side commences to darken. Viewed from the glass side both halves remain white at the commencement, but soon the half exposed from the glass side appears darker if observed in this manner. Figs. 16 to 19 are sections through films of plates exposed in this way.

In figs. 16 and 17 the back part of the plate was still white. The half No. 17 was much darker than the half No. 16, observed from the emulsion side. Fig. 16 is exposed from the emulsion side; fig. 17 from the glass side. It is quite clear that the half No. 16 must be lighter than the half No. 17, observed from the emulsion side, because fig. 16 has in its upper part less and smaller grains than fig. 17.

This comes from the fact that the part, fig. 16, has received less light in its upper parts than the half, fig. 17. The lower parts have acted as a light-filter for the upper parts of the film in the exposure from the glass side.

In fig. 17 the upper parts of the film have received the whole light, and they acted as a light filter for the lower parts of the film, situated near the glass.

The figs. 18 and 19 are results of a similar experiment, only the development has been carried on so long that the part exposed from the glass side was darker, observed from the glass side. Also this phenomenon is explained quite easily by the fact of the filtering of light. Naturally, the part of the film near the glass has received more light in fig. 19 than in fig. 18. For this reason the developer can reduce more grains and larger grains in the deeper parts in fig. 19 than in fig. 18. It can be seen from figs. 16 to 19 that in all cases the largest grains are situated in the upper parts of the film, and that a part exposed from the glass side has by no means the appearance of a part exposed from the emulsion side, inversed.

DR. W. SCHEFFER,  
Of the Scientific Staff of the C. P. Goerz A. G., Berlin.

ADVERTISEMENT Photography.—Messrs. F. Wetherman and Co., of 15, Fumival Street, London, E.C., and Enfield, Middlesex, have taken over the agency of the Ellsworth-Gross Advertisement Photographs, and have issued a book showing a few of the forcible photographs produced by Mr. Gross.

WORTHING Camera Club.—Readers are reminded that entries for the exhibition to be held from February 25 to 28, inclusive, close on Saturday, February 16. The plaques, of which two silver, ten bronze, besides medals, will be awarded, are of special handsome design. Entry form and particulars will be forwarded on application to the hon. sec., Edmund F. H. Crouch, 11, South Street, Worthing. A special additional plaque is offered in the members' class for the best indoor portraiture not taken in a studio.

#### THE ROYAL PHOTOGRAPHIC SOCIETY. THE NEW PRESIDENT.

In electing Mr. J. C. S. Mummery for their president, as they did at the annual general meeting on Tuesday last; the members of the Royal Photographic Society have recognised the wisdom of honouring that most unhonoured of all qualities in a public man, the steady devotion to the work of a society which is done in the background. Mr. Mummery, apart from his personal charms, has earned the respect of his fellow-members for the unassuming way in which he has lent the most valuable aid to the society in many directions.

For the first time since the presidency of Sir Charles Eastlake in 1856, the Royal Photographic Society has a pictorialist at its head, for Mr. Mummery is probably best known in photographic circles as a clever exponent of the gum-bichromate process, which

Photograph by] MR. J. C. S. MUMMERY, A.R.I.B.A. [T. C. Turner & Co.  
Elected President of the Royal Photographic Society, February 8th, 1907.

he uses with that wise restraint one would expect from one of his high artistic attainments. He has never been party to those extreme absurdities which have brought this process so much into disrepute.

Although everyone would place him amongst our foremost pictorial workers, he does not despise technique, and it is probably this very mastery of ordinary technique which restrains him from committing so-called "artistic" extravagances.

He has been for many years a valued member of the North Middlesex Photographic Society, and served it also as president for four years. There he has shown, too, by his demonstration of various processes, his capabilities as an elementary instructor. As was but natural from the high artistic quality of his work, he has been for some years in constant request as an art judge at various exhibitions, and has also served not only as judge, but also as one of the selecting and hanging committee for the R.P.S. exhibition, and it is an open secret that he has devoted probably as much time and care to the actual hanging as to the selection.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between January 28 to February 3:—

P.O.P.—No. 2,155. Improvements in photographic printing-out papers. William Francis Cooper, 18, Southampton Buildings, London.

P.O.P.—No. 2,156. Improvements in photographic printing-out papers. William Francis Cooper, 18, Southampton Buildings, London.

PHOTO-ENGRAVINGS ON GLASS.—No. 2,291. Photographic process for transferring designs and inscriptions to glass or stone to be engraved by means of a sand-blast. Johann Heinrich Frey and Ernest Frey, 22, Southampton Buildings, London.

BROMIDE PRINTING.—No. 2,349. Apparatus for the automatic, rapid and uniform printing, controllable at will, of positive photographs or gelatino-bromide. Adrien Cottillon, Chancery Lane Station Chambers, London.

CINEMATOPHGRAPHS.—No. 2,350. Improved apparatus for abolishing the flicker of cinematograph pictures. Julius Kopetzky, 61, Chancery Lane, London.

VIEW-FINDERS.—No. 2,359. Improvements in photographic viewfinders. Ratenower Optische Industrie Anstalt, vorm Emil Busch A.G., 77, Chancery Lane, London.

COLOUR-GRAPHY.—No. 2,461. Improvements in the bleach-out process of colour-photography. John Henry Smith and Waldemar Merckens, 65, Chancery Lane, London.

BLEACH-OUT COLOURS.—Improvements in sensitising bleach-out colours. John Henry Smith and Waldemar Merckens, 65, Chancery Lane, London.

SHUTTERS.—No. 2,485. Improvements in focal-plane shutters or other roller-blind photographic shutters. Arthur Lewis Adams, 26, Charing Cross Road, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

MULTIPLE STEREOSCOPIIC CAMERA.—No. 17,989. The claim is for a box camera provided with one pair of lenses,  $d$  and  $e$ , mounted on a panel. The box is divided into a series of compartments,  $e\ c^1$ ,  $f\ f^1$ ,  $g\ g^1$ , and  $h\ h^1$  in the figure, in each of which an exposure

can be made, the lenses being brought opposite the opening on the front. The four (or more) stereoscopic negatives are obtained on one plate. A. J. Boulton, for Antoin Cardon, Avenue de la Gare, Mentone, France.

POSTCARDS.—No. 10,878, 1906. The invention consists of a picture postcard with improved means for attaching thereto a photograph, in such manner that, while the picture is visible from the reverse side of the card, it is thoroughly protected against damage in handling, and may, moreover, be applied directly to the card without the usual delay required to permit the ordinary photographic postcard to dry.

The complete card consists of a card having a display opening

therein, a flap of thin material attached thereto at one end only, and having the other end loose with an adhesive applied to the under side, whereby the loose portion of the flap may be turned back upon itself and have a photograph or picture pasted upon it in position to register accurately with the opening in the card

when the flap is reversed and pasted down on the card. Samuel Aaron Markhoff, 74, North Main Street, Providence, Rhode Island, U.S.A.

REFLECTOR CAMERAS.—No. 3,324, 1906. The patent describes improvements to the construction of the reflex camera of patent No. 25,496, 1906. The details require the figures for explanation, but the following are the items to which protection is granted:—

1. A changer lock, actuated by means of a swinging plate carrying a mirror.

2. A mirror locking device consisting of an auxiliary tongue, connected to or forming part of the mirror lifting lever, working in conjunction with a roller stud or other suitable projection fixed to the plate carrying the mirror.

3. The combination of a double-action shutter formed of twin fan-shaped plates controlled by suitable springs and provided with studs or the like, for the purpose of engaging with various catches or detents, and a spring operated friction arm, the shutter being constructed in such a manner that, when set, both plates are detained clear of the lens aperture to allow of the adjustment and focussing of the subject, and that, when released, successive operations are performed in the following order, the closing of the lens aperture during the raising of the mirror, the opening of the lens, the release of the friction arm, and the final closing of the lens aperture, one movement being dependent on the other in the order named.

4. A bevelled spring-detent acting as a means to prevent erratic movement of the exposed plates, and also as a means of operating a spring catch detaining the mirror in the raised position, the latter operation being effected by the falling of a sheath containing an exposed plate.

5. A photographic magazine camera of the reflector type embodying:—(a). A changer lock. (b). A mirror lock. (c). An improved form of plate detent forming an automatic release for the reflecting mirror by the changing of a plate. (d). An improved form of shutter in combination with a regulating friction arm. Walter Dockree, 227, Vicarage Road, Leyton, Essex, Valentine William Edwards, 38, Brooke Road, Stoke Newington, London, N., and Houghtons Ltd., 88 and 89, High Holborn, London, W.C.

REFLEX CAMERA SWING BACK.—No. 5,673, 1906. This invention consists in the addition of a swing back, fitted to a reflex camera in such a manner that the mirror and top ground glass move together in conjunction with the focal-plane of the plate and always retains the same relative position, the movement being effected by means of a rack and pinion or other suitable means, one method being shown in section drawing, Fig. 1, G. G. G. G. being an inner plate of either metal or wood, preferably of metal, two such plates being required, one for each side of the camera, and these are held firmly together by cross bars, P. P. P. P. P., which may be placed in the position most suitable; preferably at P. P. P. P. P. The frame or inner camera so made swings on pivot A upon the pinion R, which engages with the curved rack E being put into motion. This swing of the inner part of the camera moves the focal plane shutter F. F. F., where used, also the reflecting mirror B, the top ground finder glass C, and the reversing back H at one and the same time. The dotted lines B1, C1, H1,  $f\ f^1$  show respectively the mirror, top ground finder glass, reversing back, and focal plane shutter so

moved. By turning the pinion R to the right instead of to the left, the swing is obtained in an opposite direction.

Drawing Fig. 2 shows a method of fixing the inner frame

Fig. 1.

to the camera proper, J. J. J. being metal plates screwed to the side of the camera, to which are fitted the screw pivots A and the pinion R. The plate on one side is cut away as shown

Fig. 2.

at K to allow the setting knob I of the shutter to swing clear, when the pinion R is manipulated.

The dotted lines N. N. show the woodwork of the side of the

camera proper, cut away to allow of a clear swing.—*Ernest Human*, 45, Whitta Road, Manor Park, Essex.

**ROTARY PRINTING MACHINE.**—No. 8,239, 1906. This invention relates to apparatus for the continuous printing of photographs, and has for its object by the employment of a polygonal drum a special construction to obtain an economical utilisation of the web of copying paper without waste between the copies corresponding to the various sides of the drum. The invention further comprises a special screening device which enables the employment at the same time of a water cooling system, and further, a device which frees the plates from floating particles of dust, etc., during their rotary movement, and finally devices for facilitating the introduction of the web into the apparatus.

For a full description of the apparatus the specification should be consulted. The chief claim is for a continuously operating photographic copying apparatus with a rotating drum carrying the negatives, a screen limiting the area of illumination, and a pressing apron or air cushion pressing against the drum, the copying material which is fed in a continuous web, characterised by this that the drum consists of glass under-plates abutting directly at an inclination to each other, and secured only by end discs or plates on which plates are secured, the upper plate carrying the negatives by means of edge straps, in order, on the one hand, to avoid the waste of paper by supporting straps at the meeting edges of the drum, and also to enable rapid interchange of the negatives. *Heinrich Koller*, 5, Darwingasse, Vienna II., and *Samuel Löw*, 7, Czermingasse, Vienna II.

## New Trade Names.

**BRISTLES WITH GOOD POINTS.**—No. 288,229. Photo-engravers sensitive compositions, being chemical substances included in the class. The British Gelatine Works, Ltd., New Bedford Road, Luton, Gelatine Manufacturers. (Nov. 26, 1906.)

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Passe-Partout Binding Strips.

In old days of passe-partout binding (writes Mr. S. L. Conhurst, in "The Amateur Photographer" of February 12), it was usual to cut the paper used for binding purposes and it made the process rather a tedious one, but now we can procure commercially a binding that is perfect in every way, and is the salvation of this method of framing. Dennison's passe-partout binding is the material wanted, and you cannot well do without it for all purpose. It is made in rolls of twelve yards, seven-eighths of an inch wide. It is made of fine pebbled paper, very heavily gummed, and gives not the slightest trouble in sticking. It is made in twenty-two shades and colours, but I think we, as photographers, can be well content with, say, No. 1 black, No. 2 white, No. 3 green and No. 5 brown; some workers may want No. 15 sage green and No. 4 bottle green.

### Relief Photographs.

A print should be made (writes M. Bermann in last week's "Photographic News") on stout platinotype, bromide, or chloride paper—a bust picture of, say,  $9\frac{1}{2}$  by 7 inches. Then a frame is required which can be easily made by a carpenter, of three-quarter inch wood and which should be exactly the size in the opening and look something like a printing frame. The print should be tightly stretched and well glued to this frame, so that the picture is inside.

The print should now be held up against the light, and the outline accurately drawn on the back with a pencil; in fact, everything which is required to be in relief should be drawn in. Then the back should be carefully painted with the following mixture:—

Hot glue ..... 20 parts.  
Amber varnish ..... 4 parts.

This is like a thick viscid oil. A brush should be used, and the part marked with pencil should be painted with this mixture, taking care to keep within the lines. The part painted will become elastic, and now the print should be carefully pressed towards the

front, always keeping within the outlines. The relief thus formed should be left to dry for about ten minutes, then some commercial Plasticine should be kneaded in, soft and flattened out, and the elevations of the picture filled up till the back is quite level with the part which is not raised up. Care should also be taken here not to go beyond the outlines. Then a thin board or stout miliboard should be tightly fastened to the back, and the whole turned over, so that the print is face up. It is now roughly in relief, and is modelled with a tool of hard wood or horn, with which the photograph is outlined and the shadows pressed in.

### A Time-Saving Dodge in Copying.

Whenever it has been necessary to make a copy of some definite degree of reduction in size, say one-third, one-fourth, or one-sixth, it will be found (says "Photography" in its issue of February 12) that a good deal of time is taken up in adjusting the camera. When the image on the ground glass is sharp, the scale of the picture will be wrong, and when this has been corrected, then the image is out of focus, and in focussing it up the scale is again upset. Finally, however, all is ready for the exposure.

Before disturbing the camera, after having so arranged it, let a mark be made on its baseboard with a sharp knife, showing exactly the extent to which it was opened up. The cut so made may have a little lampblack or Indian ink rubbed into it, to make it plainer, and may have marked against it the scale of the reduction. Supposing our picture is one-fifth the size of the original, we mark the baseboard—1.5. Then whenever again we have to make a copy one-fifth size, all we have to do is to employ the same lens as before, to open out the camera to the mark we have made, and then, without further alteration of it, to focus the picture by moving the whole apparatus bodily nearer to or farther from the original. When the picture is quite sharp on the screen, it must be on one-fifth scale.

## New Books.

"Photographic Studios and Dark-rooms." Edited by Paul N. Hasluck. 160 pages, 6½ by 4. London: Cassell and Co. 1s.

Like other handbooks of Messrs. Cassell's "Work" series this volume is largely made up from contributions to one of the firm's weekly journals, and therefore possesses the defects which such a method of book-making necessarily involves, that is to say, it lacks continuity. It does not state the broad principles of studio construction and proceed to their embodiment in practice. What it has to say will be less useful to the professional photographer than to the amateur, to whose perusal indeed, we can cordially recommend the chapters dealing with portable and temporary shutters, the improvisation of studios from other buildings, the making of backgrounds and the planning and fitting of dark-rooms. The illustrations in the books are very numerous—no less than 180 in number, and are well employed to explain the modes of construction recommended, yet we doubt if one amateur photographer in a hundred can profitably employ the assistance offered him in the home-manufacture of dark-room lanterns, sinks, cisterns, and other accessories which in our judgment it will be to his advantage to purchase ready made. In this criticism of the book we are not questioning the correctness of the information, but we are querying the wisdom or necessity of issuing such advice however judicious and well expressed. We are the more inclined towards this view because our perusal of the volume fails to disclose to us the answers to the elementary questions as to length of studio, proportion of glazing to solid construction; proportion of side wall to breadth and height, and the numerous other matters on which we are constantly addressed by our less experienced readers. There is a good deal about battens and joists and rebates, but on the general questions which every photographer has to become familiar with, very little.

We have to acknowledge the receipt from the author of a contribution by Dr. M. von Rohr to the "Zeitschrift für Instrumentenunde," entitled "Zur Erinnerung an Josef Max Petzval." Dr. von Rohr reviews Petzval's career and discusses the optical properties of the celebrated large-aperture lenses first made from his calculations by Voigtländer.

## New Materials.

Satino Carbon Paper. Sold by the James S. Nunn Company, Ltd., 11, Queen Victoria Street, London, E.C.

The appearance of a pigment paper upon the market in which the permanency of the carbon print could be obtained by the simple operations of printing and development will naturally arouse much interest, particularly among photographers who set permanency before other considerations in the choice of a printing process. It should be said at the outset that the "Satino" paper is quite unlike carbon tissue; unlike it, apparently, in composition and totally unlike in it in the treatment which it receives in the operations of development. It resembles carbon tissue in the need of an actinometer, although the claim is made by the makers that, with experience, the stage of correct exposure may be recognised by eye. The paper is sensitised by immersing first for one minute in a bath of methylated spirit, whence, without washing; it is transferred to the sensitiser proper, a solution of potassium bichromate of about 1 per cent. strength. In this it is allowed to remain for two minutes. The paper, after drying, is exposed in the usual way. Development proceeds as follows:—The print is placed in a dish of cold water for a moment, and then rinsed *under a rose* for about three minutes. This treatment is necessary to remove the apparent greasiness of the surface and to allow the water to run evenly over its surface. It is then placed in warm water (about 112 deg. Fahr) in which the image appears. The positive image of full strength is not obtained until applying the rose jet, a very heavy pressure of which the surface of the "Satino" print appears to resist with impunity. The nature of the finished print is seen to be of an extremely fine grain, producing in the shadows a very intense black deposit, and in the half-tone a characteristic appearance, which may be described by "silvery" better, perhaps, than by any other word. The makers in their instructions detail the manipulation of the paper at considerable length, yet there is one point to which, we think, they should draw attention, and that is the extreme delicacy of the pigment surface when the paper is in a wet state during sensitising. In our experience, the greatest care was needed to avoid removing the pigment, and it would seem that with methylated spirit, of the quality which is obtainable in this country, a longer immersion of the paper than one minute may be advised, in order to impart the necessary resistance to the film of the paper.

The only other point at which the beginner is likely to make a mistake is in the development. The difference between the behaviour is so great that the inexperienced may be inclined to put a print down as over-exposed, because it is slow in developing, whereas the reason of the slow appearance is probably due to a fear of injuring the surface under the rose. "Satino" is sold in cut pieces, in packets, which are priced on the basis of eight quarter-plate pieces, for 6d. The larger sizes, half-plate and whole-plate, are put up in packets of four pieces.

U-form Binding Strips. Made by the Trocken-Bindstreifenfabrik (Dr. J. Neubronner), Cronburg in Taunus.

Since the reference to the lantern slide binding strips of the above-mentioned firm, we have received, through Messrs. Dallmeyer, an outfit, consisting of the binding strips in the strip and roll form, fixing iron, and lamp. The strips are sold in lengths of two ¾-inch sections, or in rolls of 25 and 50 yards length. In the case of the former a V-shape is given to the ends of each piece, so that when all four pieces have been applied to the slides there is no thickening from overlapping. In addition to this, both the strip and roll binder, which is half an inch in width, is slightly indented on the coated side along two parallel lines 1-16th of an inch apart, down its centre, as a result of which it is easy to apply the binder centrally and uniformly to the slide.

The adhesive preparation on the binder is softened, not by moisture, but by heat, in a manner which, so far as we may judge from the behaviour of the strips in practice, appears to be that of the adhesive tissue of the Derepas patent, controlled in this country by the Adhesive Dry Mounting Company, of Fetter Lane, E.C. Our examination of the binder has not enabled us to say whether

if differs from the adhesive "tissue," but, at any rate, it possesses in practice the good qualities of the dry mounting process, the attachment in the case of the binder being made by a heated tongs, as shown in the drawing, and producing a binding of the neatest

and most permanent description. The price of 100 strips (for 50 slides) is Mk. 1.50 (1s. 6d.), and of the heating tongs, Mk. 3.50 and Mk. 4.0 (3s. 6d. and 4s.).

#### CATALOGUES AND TRADE NOTICES

THE "Camera House Journal" (W. Butcher and Sons), in its January issue, just received, publishes reproductions of the six coloured covers of catalogues which can be supplied to dealers on advantageous terms. Application may be made to Camera House, Farringdon Avenue, E.C.

A 48-page bargain list of apparatus which, though shop soiled, is guaranteed in thorough repair, has just been published by the Tella Camera Co., 110, Shaftesbury Avenue, London, W. A variety of lenses, hand and stand cameras, and other apparatus is offered at greatly reduced prices. The firm makes a special feature of accepting customers' apparatus in part payment for purchases.

MESSRS. SPIERS AND POND send us their very full catalogue of photographic requisites, a copy of which they will send to any applicant.

## Commercial & Legal Intelligence.

**A LIBEL ACTION.**—At the Hertfordshire Assizes on Saturday last, Valentine Crick, a grocer's assistant at Bishop's Stortford, sued a photographer, named Bruxley, of the same town, to recover damages for an alleged libel. The plaintiff's case, which arose from circumstances already reported in THE BRITISH JOURNAL OF PHOTOGRAPHY, was that in December of 1905 he had six photographs of himself taken by the defendant on postcards, for which he paid 1s. 6d. Afterwards he ordered six more, but told the defendant that he was in no hurry for them. He delayed going for them, and in the following June, as he was passing the defendant's shop, he saw one of his (the plaintiff's) photographs exhibited, with the notice attached, "This is the man who puts his hair in curls to have his portraits taken, and then cannot pay for them." This was the libel complained of, the plaintiff alleging that it was untrue to say that he curled his hair, as it curled naturally, and that he had suffered annoyance from the notice. The defendant pleaded justification, though he admitted that he was wrong in putting the notice in his shop window, and said he would have apologised for it if he had been asked to do so. In the result the jury gave a verdict for the plaintiff with a farthing damages. Judgment was entered accordingly, with costs.

**CHARLES TYLER AND ENGLAND BROTHERS, LIMITED.**—Issue on December 6 of £10,000 five per cent. debentures, part of series created by resolutions of April 12, 1902, and December 6, 1906, to secure £20,000. Property charged—The company's undertaking and property, present and future, including uncalled capital. No trustees. Total amount previously issued of same series, £10,000. This is an amended return, in substitution for that filed on December 19 last, in connection with the registration of the £10,000 debentures dated December 6, 1906. The original return did not mention that the said £10,000 formed part of a series of £20,000, of which £10,000 were already issued.

**INDECENT PHOTOGRAPHS.**—Frederick Griffin, 23a, Clayton Road, Bradford, was summoned last week before the Bradford Stipendiary Magistrate (Mr. C. Skidmore) to show cause why certain obscene photographs should not be destroyed. The Chief Constable (Mr.

J. Farndale) applied for an order of destruction of ninety-eight negatives and 350 photographs. Mr. Skidmore made the order for destruction and an order for costs on the defendant, against whom, it was intimated, further proceedings will be taken.

#### NEW COMPANIES.

**INTERNATIONAL PROJEKTOGRAF COMPANY.**—Capital £200,000 (£20). To acquire inventions relating to the patent ProjektoGRAF, for improvements in projection apparatus for photographs, pictures, etc., and to adopt an agreement with T. Ficker. No initial public issue. First directors (not less than three nor more than seven): T. Ficker (chairman), F. Friedmann, and O. Jammer. Qualification, £100.

**ROMANI MINIATURES.**—Capital £5,000 (£1) (2,500 preference). To acquire the business of a manufacturer and vendor of tinted photographs (framed and unframed) carried on by F. de Paul Romani, at 51, Esmine Road, Ladywell, as the Souvenir Miniature Company. No initial public issue. First directors: F. de Paul Romani, one other nominated by him, and not more than three others to be appointed by signatories. Ordinary qualification, £100.

## Meetings of Societies.

#### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, FEBRUARY 15.

West London Photographic Society. Annual Exhibition of Members' Work. Sutton Photographic Club. "A Chat on Lenses." E. A. Salt.

SATURDAY, FEBRUARY 16.

Aberdeen Photo Art Club. "To Norway o'er the Faem." W. R. Macgregor.

MONDAY, FEBRUARY 18.

Southampton Camera Club. "Legitimate Control in Photography." Demonstration. C. H. Hewitt. Stafford Photographic Society. "Enlarging." G. Wray. Catford and Forest Hill Photographic Society. "Bromide Printing and Toning." A. H. Dunning. Blackburn Camera Club. "Scenes in Holland and Germany." C. L. Fauntleroy. Preston Camera Club. "Among the Dutchmen with a Camera." J. T. Ferguson. Lancaster Photographic Society. "A Holiday Tramp." Illustrated. G. W. Barrow. South London Photographic Society. "A Tour Round the World." C. Marshall. Kings Heath and Moseley Photographic Society. "Dutch Scenes and People." Arthur Marshall. Cleveland Camera Club. "Enlarged Negatives on 'Rotograph' Negative Paper." Wilsden Polytechnic Photographic Society. "Stereoscopic Photography." C. P. Goetz.

TUESDAY, FEBRUARY 19.

Royal Photographic Society. "All at Sea with a Hand Camera." F. J. Mortimer. Birmingham Photographic Society. "Photography in Relation to Art." Rev. H. W. Dick. Sheffield Photographic Society. "The Dales and Coast of Yorkshire." Godfrey Bingley. Blyth and District Camera Club. "Intensification and Reduction." W. French. Darlington Camera Club. "With Cycle and Camera in Scotland." W. Wilson. Hackney Photographic Society. Annual Dinner. Worthing Camera Club. "With the Camera in the North." T. Roberts. R.F.S. Redhill and District Camera Club. "S.C.P. Lantern Plate." A. H. Dunning. For Messrs. Wellington & Ward. "Stereoscopic Photography." H. Payne. Heaton and District Camera Club. "Enlarged Negatives on 'Rotograph' Negative Paper." Acton and Chiswick Polytechnic Photographic Club. "Telephotography." C. P. Goetz. Otley Camera Club. "What Can be Done with a Hand Camera." C. P. Goetz.

WEDNESDAY, FEBRUARY 20.

Bristol Photographic Club. "Bromide Printing." F. Little. Birmingham Photographic Society. "Enlarging and Printing on Bromide Paper." E. D. Taylor. Hampstead Scientific Society. Annual Lantern Slide Competition. I.C.C. School of Photo-Engraving. "Calligraphy." Edward Johnston. North Middlesex Photographic Society. "Photographic Optics." J. McIntosh. Borough Polytechnic Photographic Society. Fourth Lantern Slide Competition. Everton Camera Club. "Scottish Union Print Folio." Tunbridge Wells Amateur Photographic Association. "A Dive into Belgium." W. L. F. Wastell. Leicester and Leicestershire Photographic Society. "Lantern Slides." W. E. Barton. "Is Photography Justifiable?" J. E. B. Hales. Morphett Y.M.C.A. Camera Club. "Enlarged Negatives on 'Rotograph' Negative Paper." Rochdale Amateur Photographic Society. "Theory and Practice of Self-Toning Papers." Wolverton Photographic Society. "Sports and Pastimes with the Goetz-Anschütz Folding Camera."

THURSDAY, FEBRUARY 21.

Chelsea and District Photographic Society. Annual General Meeting. I.C.C. Staff Camera Club. "Mounts, Mounting, and Mountants." P. S. White. Blenheim Club. "Athletics and Sculpture." S. C. Kaines Smith, M.A. Richmond Camera Club. "Hampton Court." T. H. Blythman. Rugby Photographic Society. "Telephotography." Ernest Marriage, F.R.P.S. Liverpool Amateur Photographic Association. "The Sun—Our Luminary." W. Hewitt, B.Sc. London and Provincial Photographic Association. "Modern Printing Processes." Archer Clarke.

andsworth Photographic Society. "Lantern Exhibition—North Eastern Railway slides."  
 North London Photographic Society. "Figure Studies." E. H. R. Hillsworth.  
 Underland Photographic Association. "Enlarged Negatives on 'Kotograph' Negative Paper."  
 Hull Photographic Society. "Gum Ozotype." J. F. Copley.

### PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the General Committee was held at the Royal Photographic Society, 66, Russell Square, W.C., on Friday, February 8. Present, Messrs. A. Ellis, S. H. Fry, H. E. Hull, A. Mackie, Prodder, E. Scamell, Lang Sims, R. W. Robinson (Redhill), and H. C. Spink (Brighton). Mr. A. Ellis in the chair.  
 The draft annual report was read and passed, and arrangements in connection with the annual general meeting on March 8 were discussed.

The Hon. Secretary reported that he was making arrangements with the Fine Art and General Insurance Company in connection with the Employers' Liability Act, and full particulars would be published in the next Circular, to be published in about a fortnight. A long discussion took place regarding a case where a member had been defrauded by an individual, against whom there appears to be many other cases. Eventually it was agreed to take certain steps in view of instituting a prosecution.

### ROYAL PHOTOGRAPHIC SOCIETY.

ANNUAL general meeting held February 12, Mr. J. C. S. Mummery in the chair.  
 The "Progress Medal" for the year 1906 was presented to Mr. Sanger-Shepherd.

The meeting then proceeded to discuss the report of the Council and the balance-sheet for 1906. In reference to the society's financial situation, the treasurer (Mr. John Sterry) announced that since the commencement of the year subscriptions to the amount of £50 had been received, bringing the deficit in the income and expenditure account to £44. Mr. Sterry remarked on the needless expense to which the society was put by members who failed to pay their subscriptions within the year. He estimated that each subscription which was not obtained until after several applications meant a loss to the society of two shillings.

The sections of the report were then discussed paragraph by paragraph, and elicited little comment, until that referring to the society's Journal was reached. Mr. E. J. Wall said that in view of the increasing difference between the receipts from the sale of the Journal and from the advertisements in it and the cost of production, it was necessary to take steps to employ a less expensive form of production, although one which, nevertheless, would equally serve the society's purpose. He thought that an unnecessary amount was spent on the paper for the Journal. At the time it was selected the idea was to print half-tone blocks on it, but the speaker noticed that very few blocks were used, and, in fact, when a block of any kind was employed in the Journal an art paper was inserted to it.

Mr. C. E. K. Mees complained that insufficient supervision was given to the publication of the papers and addresses read before the society. He thought the Journal was conducted with greater laxity than in many similar publications. Its obvious defect, he said, was that it was not edited. Many papers had no business to appear in it, and he suggested that a committee might deal with papers read before the society and published in the Journal in order that much-needed abridgement might be carried out by the author or by a member of the committee qualified to do so.

Mr. George E. Brown said that it should be axiomatic that elementary matters to be found in text-books, as well as lengthy reports of "Lectures," should be practically excluded from the Journal, and that the detailed reports of the Affiliation were of little value. Mr. McIntosh, appealed to by the Chairman, expressed the opinion that an editorial committee could not successfully undertake the selection and prompt publication of the journal.

Mr. Bale Rider begged that the function of the Journal as the organ of the society's proceedings should not be lost sight of.

Mr. W. Thomas thought that previous speakers, in suggesting means to counterbalance the diminished advertisement revenue of the society's organ, disregarded the fact of the greater competition of photographic publications. He would strongly protest against the omission of the Affiliation's proceedings from the Journal.

In the discussion of the exhibition, Dr. Evershed asked what amount had been received as admission money from the sale of Affiliation tickets. The amount was stated to be £95. Dr. Evershed thought that a large proportion of this sum would not have been spent but for the distribution of the tickets in the Affiliation Red-Book.

Mr. Armytage Sanders drew attention to the inconvenience caused to exhibitors at the New Gallery by the want of a telephone service during the exhibition. He thought exhibitors and others would gladly pay for this privilege if it could not be obtained from the management of the New Gallery.

The Chairman then proposed that the thanks of the society should be offered to the retiring President, Major-General Waterhouse, for his constant and valuable services to the society during his two years of office. The proposition was seconded by Mr. Leslie Clift, and carried with much enthusiasm.

A vote of thanks to the council and officers of the society was proposed by Mr. George Scamell, and seconded by Mr. F. T. Beeson. Mr. McIntosh briefly replied. Mr. Sterry proposed a vote of thanks to the honorary auditors, Messrs. Calder, Marshall, Son, and Ibbotson, which was similarly carried, and the Chairman then called upon Mr. W. T. P. Cunningham to present the report of the scrutineers of the ballot. The following proved to be the newly-elected officers of the society:—

PRESIDENT.—J. C. S. Mummery.

VICE-PRESIDENTS.

Sir W. de W. Abney. Sir Joseph W. Swan.  
 The Right Hon. the Earl of Major-General Waterhouse.  
 Crawford.

TREASURER.—John Sterry.

COUNCIL.

A. W. W. Bartlett.	Furley Lewis.
Henry W. Bennett.	Ernest Marriage.
Leslie E. Clift.	Arthur Marshall.
A. R. F. Evershed.	C. E. Kenneth Mees.
T. E. Freshwater.	F. J. Mortimer.
John H. Gear.	C. Welborne Piper.
E. T. Holding.	E. Sanger Shepherd.
Fred Hollyer.	J. Spiller.
C. Lindsay Johnson.	H. Snowden Ward.
Rev. F. C. Lambert.	B. Gay-Wilkinson.

JUDGES IN THE TECHNICAL SECTION.

Thomas Bolas.	E. Sanger-Shepherd.
Chapman Jones.	Sir Joseph Swan.
C. E. Kenneth Mees.	E. J. Wall.
Major-General Waterhouse.	

The report of the ballot was received with applause, Mr. Mummery, on his official election to the presidency, being the recipient of a perfect ovation.

**SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.**—At a full meeting of the organising committee held at 27, High Street, Lewisham, on Wednesday evening, with Mr. A. Haddon in the chair, it was decided that this society should be known as the South Suburban Photographic Society, and that steps should be at once taken to secure headquarters at Lewisham Junction. The Royal Observatory Camera Club was represented at the meeting by Messrs. H. Furner and P. Melotte; and there were also present Messrs. J. F. Ashby, A. E. Bennetto, P. C. Cornford (ex-secretary of the Borough Polytechnic P.S.), Thos. K. Grant, J. D. Murray, J. Nixson (hon. sec.), H. A. Robinson, and Chas. Stuart (the host of the occasion). The hon. secretary of the Catford and Forest Hill Photographic Society (Mr. W. T. Browne) also attended. Eight new members were added to the committee, including the Astronomer Royal, and Messrs. Vivian Orchard (Town Clerk of Deptford), Francis L. Robinson (Town Clerk of Greenwich), P. C. Cornford, and E. W. Andrew (former secretary of the Bromley Camera Club). The Astronomer Royal was provisionally elected president, and it was resolved to invite the M.P.s and Mayors of Greenwich, Lewisham, and Deptford, Canon Barnes-Lawrence, Rev. W. W. Hough (Vicar of Lewisham), Messrs. C. Welborne Piper, F. J. Mortimer, T. K. Grant, A. Haddon, and other well known amateurs to take office as vice-presidents. Mr. E. W. Andrew, of 12, Old Dover Road, was also elected joint hon. secretary, and as a result of the meeting we understand steps will be taken to complete the organisation as early as possible and to appeal to the photographers of the three boroughs to throw in their lot with the society.

**EDINBURGH PHOTOGRAPHIC SOCIETY.**—Mr. A. Wallace McGregor, a lawn tennis player of some note, read a paper at the meeting last week, on lawn tennis photography. The lecture was illustrated by a variety of slides which Mr. McGregor had chosen mainly for the purpose of showing as far as possible the styles and strokes of most of the best players, as also the varieties of background and light to be met with at many of the leading tournaments both at home and abroad. The grotesque positions in which the camera depicted some of the players in the courts evoked much laughter, and drew forth some comment in the discussion which followed. Mr. A. H. Baird, president, occupied the chair, and conveyed to Mr. McGregor the thanks of the meeting.

**KINGS HEATH AND MOSELEY PHOTOGRAPHIC SOCIETY**, recently formed in conjunction with the Kings Heath Literary Society held their fortnightly meeting on Monday, before a good attendance of members, with the president, Mr. J. Page Croft, in the chair. Mr. A. R. Teague, secretary of the Handsworth Photographic Society, gave an address and demonstration on "Bromide Printing." Mr. A. Roffey in his demonstration on "Gaslight Printing" produced some wonderful effects with papers having a beautiful variety of tints. The Hon. Sec. will be pleased to hear from any lady or gentleman wishing to join. His address is Livingstone Road, Kings Heath.

**CROYDON CAMERA CLUB.**—A discussion on "Easy Printing Processes" took place on the 6th inst., the pros and cons of most printing mediums being considered. Messrs. F. W. Hicks and F. J. Terry ably championed platinotype, Mr. H. P. C. Harpur, carbon; Mr. S. H. Wratten put in a good word for P.O.P.; and Mr. H. T. Dodsworth sent a letter dealing with self-toning papers. The bromide process, curiously enough, remained unrepresented, though it should have been a strong competitor. On the other hand gas-light papers found favour, mainly on the ground that they gave the best translation of the average negative produced by the beginner. That any definite conclusion was arrived at as to the "easiest process" cannot be said, the debate ultimately arousing a feeling of partisanship, hardly conducive to an impartial examination of the subject, though eminently calculated to add to the cheerfulness of the evening. Mr. E. A. Salt showed Messrs. Lumière's "Actinos" paper, a P.O.P. containing no soluble salts, and stated to keep indefinitely and be unaffected by damp. He also fixed a glass negative and a Sandell film in their new "Fixoline," or acid-fixer. Briskly boiling water was then poured on both negative and film without ill effect, except that the gelatine of the glass negative showed slight signs of pitting, which would probably disappear on drying. Users of Sandell films, he thought, might safely dispense with the preliminary formaline bath recommended, and employ the acid-fixer to attain the same end. For the rapid washing and drying of negatives and papers, such a bath would obviously be most useful. Dr. Mees then exhibited and explained a series of contrast and other filters for photo-micrographic work (a full account of these, and the principles underlying them, appeared in our last issue.—Eds. "B.J."). Their production, he said, had directly arisen out of a lecture recently given by Mr. Bawcomb at the Croydon Camera Club. Mr. Bawcomb said that all photo-micrographic workers were under a debt of gratitude to Dr. Mees and Messrs. Wratten and Wainwright. Hitherto there had been very little published on the matter; the usual directions given for photographing difficult stained subjects—viz., to employ a filter of complimentary colour to the stain—being very vague and unsatisfactory. Thanks to the sharp spectral cut of the filters now introduced, and the plain directions issued for their use, he had been able to obtain first-rate photo-micrographs of subjects impossible to render adequately before.

**CENTRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.**—On Wednesday, February 6, Mr. E. Walter Maunder, F.R.A.S., Superintendent of the Solar Department of the Royal Observatory, Greenwich, gave a most interesting lecture on Astronomical Photography. The lecturer, after giving a brief history of early work in photography as applied to astronomy, including J. W. Draper's Daguerreotypes of 1840, described the present uses of photography at the Greenwich Observatory, and showed how very much greater accuracy was obtained when the continual movement of instruments could be recorded. In many cases, the lecturer stated, deflections of the

magnetic needle were recorded which would have probably remained unnoticed had it not been for the constant record. Much of interest was told about sunspots, it being pointed out that they went through their changes in a slightly variable cycle, and that the daily swing of the magnetic needle follows this directly. Many interesting photographs and transparencies were shown representing much of the work of the observatory. Very hearty votes of thanks were passed to the lecturer, and to Prof. W. E. Dalby, M.A., B.Sc., M.Inst.C.E., for taking the chair.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—At the meeting on Thursday, the 7th, Mr. W. Thomas in the chair, the first of the series of elementary lectures was given by Mr. J. S. Teape, who demonstrated the making of lantern slides. He said that his aim was to explain a system of making lantern slides so as to avoid a waste of plates and materials. The factors to be considered in making lantern slides were: 1, the negative; 2, the light; and 3, the developer. As regards exposure he recommended a test frame which consisted of an ordinary printing frame with a shutter of thin wood marked in  $\frac{1}{4}$  inches, so that a series of exposures could be made, and thus the proper exposure for each class of negative obtained. He also recommended a printing board. The one shown was marked in three-inch divisions, with two blocks of wood at one end of sufficient distance apart to just take the printing frame, the light (a fish-tail gas-burner) being movable, and placed upon the division line in use. He also had a pair of small zinc squares, which were useful for deciding what part of a negative to use for the slide, thus enabling him to put the desired part central upon the lantern plate. A half-plate frame was used when printing from  $\frac{1}{4}$ -plate negatives, cardboard mask to take the negative enabling the worker to square up any line out of truth. Mr. Teape strongly recommended the following developer:

No. 1. Hydroquinone	2 drachms
Sulphurous acid	1 drachm.
Potass. bromide	30 grains.
Water	10 ounces.
No. 2. Caustic soda	2 drachms.
Soda sulphite	10 drachms.
Water	10 ounces.
No. 3. Potass. bromide	2 drachms.
Ammon. carbonate	2 drachms.
Water	5 ounces.

This was used. Nos. 1 and 2, 2 drachms of each, and 1 ounce of water. The formulæ as issued by the makers, he said, often gave bad results with blocked up shadows, and should, when used, be diluted with water. A good yellow light was preferred to ruby in the dark-room when making slides, and the No. 3 solution was only used for coloured or toned slides by development. Slides were then made by the lecturer, and a collection of slides from one negative showed the plates used being Hford "Alpha" and Paget "Slow." Using the first named a fine brown was obtained by 30 seconds' exposure at 6 ins. from a fish-tail burner and with the normal developer: with 60 seconds' exposure a warm brown was obtained, with 60 seconds at 12 ins., black, with the same at 18 ins. a cold black, whilst with 60 seconds at 6 ins. and the addition of 3 minims of No. 3 solution a red was obtained. Using the Paget "Slow" 20 seconds at 12 ins. gave a blue, 40 seconds at 12 ins. with 40 minims of No. 3 a brown; 60 seconds at 12 in. with 40 minims of No. 3 a warm brown; 100 seconds at 12 ins. and 60 minims No. 3 a very fine warm brown; 60 seconds at 12 ins. and 100 minims of No. 3 a red, this latter taking just one hour to develop. It was, he said, a curious fact that the colour appeared much warmer when viewed out of the lantern. For instance a slide apparently of a red colour would be brown when on the sheet. The chairman said the demonstration had struck him as being one by a practical worker, and it was certain that many useful hints had been given. Mr. Freshwater proposed and Mr. Haddon seconded a hearty vote of thanks to Mr. Teape.

Mr. J. E. HODD, F.R.P.S., we learn has vacated his position. Messrs. W. Butcher and Sons, to join the Westminster Photographic Exchange, 119, Victoria Street, S.W., where his long experience in photographic dealing, gained from his managership of Messrs. Spiller and Pond's photographic department, and later of that of the Army and Navy Stores, should be of the greatest service to the Westminster Exchange.

## News and Notes.

**GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.**—The annual exhibition of the Glasgow and West of Scotland Amateur Photographic Association, in their rooms, 180, West Regent Street, Glasgow, shows an increase in the number of prints, and a decrease in the lantern slide entries. A non-competitive class gives us an opportunity of seeing some of John Hepburn's genuine subjects. The judges were Messrs. J. Craig Anzan, Maurice Greiffenhagen, and Wm. Goodwin, and bronze plaques were given to them to award at their discretion. In the nine classes, they awarded plaques to Dr. A. Richmond; J. Duncan Leslie, Chas. J. Bryden, James McKissack (2), J. MacWilliams (2), John A. Stewart, John Norman, junior, A. Herbert Brown, A. R. McCormick, A. J. Garwood (2), Richard Prosser, E. T. Goslin, Jas. G. Wilson, D. M. Filshill, John Cuthbertson, John Young, and John W. Downs.

Mr. GRAYSTONE BRID, of Milsom Street, has just scored a century of photographic exhibitions, having been awarded his hundredth medal, or plaque. All these prizes, which include several gold and silver champion medals as well as ordinary silver and bronze medals, have been obtained at exhibitions which are open to all the world, and were awarded for landscape, seascapes, sky effects, out-door genre studies, and especially pictures of children taken in his studio. Mr. Brid has also won about 80 other prizes, a number of which were for hunting and steeplechase pictures. It is few photographers who have secured such a record in 10 years.

A new electric lamp filament has been discovered by Professor F. C. Parker and Mr. W. G. Clark, of Columbia University, U.S.A. The Helion filament, as the inventors call it, gives a very white light and only requires one watt per candle power. Comparison between the luminosity of a Helion filament and the ordinary lamp showed that the former gave three and a half times the amount of light with considerably less energy for the same wave length. This high efficiency was thought to be largely due to selective radiation. The life of the new filament, which consists chiefly of silicon on a thin carbon core, so far appears most satisfactory though conclusive tests are wanting, and the drop in candle power is small even with a run of over a thousand hours. As the ordinary vacuum lamp bulb is used, and about twice the quantity of light with half the consumption of electricity is obtained there should be a big future before the new lamp.

**LUMINOUS EMISSION.**—The fact that a luminous emanation of variable shape will appear in the dark at such points on the surface of the earth below which there are extensive ore deposits at a more or less considerable depth, was recorded in Germany as far back as 1747. Immediately before or during a thunderstorm these phenomena are said to be especially striking. Similar observations have more recently been made in North America in the neighbourhood of ore deposits. Though much should be ascribed to superstition and errors of observation, the fact nevertheless has been confirmed by recent investigation. The electric emanation given off from the surface of the earth (see *Prometheus*, No. 891) has in fact been repeatedly ascertained photographically by Mr. K. Zenger. Plates coated with fluorescent substances were used. It may thus be taken for granted that the emanations in question occur with an especially high intensity at those points of the ground where good conductors of electricity are found in large amounts in the neighbourhood of the surface of the earth, in other words, above ore deposits, which are very good conductors of the electric current. Lignite and coal, especially when containing pyrites, are fairly good conductors. The difference in the intensity of radiation as compared with points free from any ore would seem to be recognised by means of photography, thus affording to geologists a rather simple means of locating ore and even coal deposits.

"The Photographic Department, its Inception and Management," a reprint of a series of articles on photographic dealing by Mr. C. H. Wallsgrove, reaches us from the author's firm, Messrs. Hands and Co., of Bletchley, by whom a copy will be sent free on application. The booklet deals with many points in a dealer's business, such as the stocking of chemicals, mounts, and albums, plates and papers, and apparatus. The author also discusses the management of a dark-room for customers, and the execution of developing and printing orders.

**THE Supply of Platinum.**—The "South African Mines" lately published an article by Mr. William Bettel, a well-known specialist, on the existence of platinum in the Transvaal. As far back as 1890 Bettel had discovered platinum in the sand which came from a mine in the district of Klerksdorp. Only about 50 milligrammes of platinum was obtained, but still sufficient to justify the belief that platinum was to be found in the Transvaal, and not only in infinitesimal quantities. Further research has confirmed this opinion. In February, 1906, Mr. Bettel examined some small quantities of mineral from which gold had been extracted by some prospectors in the neighbourhood of Klerksdorp, and the chemical analysis gave the following result: Platinum, 12 per cent.; iridosmine, 76.17 per cent.; iridium and rhodium, 7.50 per cent.; gold, 1.04 per cent.; sand, 0.65 per cent.; various metals, copper, iron, etc., 2.64 per cent. Again, quite recently, Mr. Bettel analysed half-a-dozen samples of iron chromate minerals which afforded 1.10 to 1.6 per cent. of platinum. Mr. Bettel has not been authorised to reveal the district from which these samples came, but he declares that the platinum in them came from an old volcanic rock, and adds that as the actual price of platinum is higher even than that of gold, attention should be devoted to the discovery of this precious metal.

A report in the "Franklin Institute Journal" gives the following figures for the production of platinum in 1905:—The production of platinum from domestic ores in 1905 was 318 ounces, valued at \$5,320, as compared with 200 ounces, valued at \$4,160 in 1904; with 110 ounces, valued at \$2,080 in 1903; with 94 ounces, valued at \$1,814 in 1902; with 1,408 ounces, valued at \$27,526 in 1901; and with 400 ounces, valued at \$2,500 in 1900. In December, 1904, the price of ingot platinum at New York advanced from \$18.50 to \$19.50 an ounce; in April, 1905, it was \$20.50; in February, 1906, it advanced to \$25, and in September, 1906, it was \$34 an ounce.

**THE Franco-British Exhibition**, to be held in London next year, has been warmly endorsed by the King during his stay in Paris last week. A guarantee fund of £220,000 has already been accumulated.

**SIR JOSEPH SWAN.**—The Council of the Society of Arts attended at Marlborough House on Friday last, when his Royal Highness the Prince of Wales, President of the Society, presented the Society's Albert Medal to Sir Joseph Wilson Swan, F.R.S., "for the important part he took in the invention of the incandescent electric lamp and for his invention of the carbon process of photographic printing."

**THE Scottish Salon.**—This exhibition retains its hold on the affections of Scottish workers. No prizes are offered and no entry money is charged; a place on the walls is the award of merit, and this award seems to be valued, as the entries for this year considerably exceed all previous records. The Board of Selection met on Thursday and had a work of no little magnitude in selecting the pictures for hanging. The opening ceremony will be held in the Art Gallery of the Museum, Paisley on the 23rd inst., at twelve noon, and the official lunch is due an hour afterwards. On the 22nd inst. there will be a private view and reception of delegates. The exhibition will remain open for three weeks, and a full and interesting programme of lectures, music, etc., has been arranged for the evenings.

**FLASHLIGHT.**—An American photographer, Mr. D. G. Archibald, of 119, Miller Street, Newark, U.S.A., informs us that he will be pleased to receive catalogues of flashlight apparatus and materials which will be of use to him in a work on flashlight photography which he is compiling.

**SPEED Test of Shutters.**—Messrs. A. E. Staley and Co., 19, Thavies Inn, E.C., write:—We are enclosing herewith dummy sheet of the test card which we are about to furnish for all shutters sent to us for testing. We shall charge sixpence each for testing, which will include any make of shutters, focal plane or otherwise. A considerable amount of time has been spent on the testing apparatus, and we can furnish a very good chart of the actual speeds. As the representatives of the largest shutter makers in the world (Messrs. Bausch and Lomb), we have frequently been asked if we would undertake the testing of shutter speeds. We now wish to say that we shall be pleased to undertake this work.

**A COLOUR Photography Society for America.**—In reference to the recent formation of the "Society of Colour Photographers" in this country, the suggestion of a body with a similar name in the United

States is made by Mr. F. C. Beach in the "American Amateur Photographer and Camera and Dark Room." Mr. Beach will be glad for supporters of the proposition to address him at 361, Broadway, New York.

**The Lizars Competition.**—The prize pictures in the recent "Challenge" competition will be exhibited at 251, High Holborn, London, from February 21 to 28, when Messrs. Lizars will be glad to see any of our readers who may be interested. Arrangements have been made with the South London Photographic Society to include the pictures in their annual exhibition, which will be held at the Camberwell Baths from March 2 to March 9.

"The American Amateur Photographer" and the "Camera and Dark Room," two of our monthly contemporaries in the U.S.A., which have been under the same management for some years past, have now been united into one publication, "The American Amateur Photographer and Camera and Dark Room." Features of the latter publication are to be retained, and the editorial staffs join forces in the new publication, which is issued by the American Photographic Publishing Co., 361, Broadway, New York.

**W. H. SMITH AND SONS.**—Though Messrs. W. H. Smith and Sons, as bookstall newsagents, have been before the public for nearly half a century, it is news to most people to hear that for little short of that time they have been pioneers in various departments of art printing in their works in Fetter Lane, E.C. They have now established, at No. 95 in the same narrow thoroughfare, under the control of Mr. H. E. Morgan, a gallery, reference library, and consulting rooms, where intending customers may examine an immense variety of styles and design in letterpress and illustrative printing. Our acceptance of an invitation last week gave us the opportunity of seeing some samples of circular and booklet printing such as bear out Messrs. Smith's claims to be able to produce enclosures which require some description more dignified than "printed matter." To single out one circular only, that for Messrs. Rackham and Co., costumiers, of Birmingham, here is a refined production, which a first-rate photographer would feel confident in accepting as a medium of appeal to his public.

At the L.C.C. School of Photo-Engraving and Lithography, Bell Court, Mr. Oliver Dawson lectured on February 7 on "The Bleach-Out Process of Colour Photography." He explained the principle on which the paper, as made by J. H. Smith and Co., was prepared and exhibited a number of copies of coloured originals made on the paper. Mr. R. Reynolds exhibited the results of direct copies of leaves, flowers, and wings of butterflies made on the paper, and Mr. W. Sage referred to the great difference in the exposures in London and the country.

## Correspondence.

\**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

\**We do not undertake responsibility for the opinions expressed by our correspondents.*

MR. CHAPMAN JONES AND THE R.P.S.

To the Editors.

Gentlemen,—I shall be glad if you will allow me, through your columns, to offer my sincere thanks to those members of the Royal Photographic Society who continue to nominate me to various offices in the society, and to briefly explain my position. In November, 1896, certain changes were determined upon that the president (Sir William Abney) and the hon. secretary (myself) felt would not be for the society's welfare. To avoid the false position that would otherwise have ensued, Sir William Abney and I resigned. Shortly after this I was elected a vice-president. The spirit of unrest continued to assert itself, and matters grew more acute until the election in February, 1902, when the late Mr. T. R. Dallmeyer and I were nominated to the presidency, Mr. Dallmeyer by those who wished for certain changes, and I by those who deprecated the most important of them. The votes showed a large majority in favour of the "reform party," and nearly all the members of the old council were rejected. Since then I have attended no meetings of the society, except that I have continued to serve on two committees at

the special request of the new council. In each of the five ensuing years, however, I have been nominated to the positions of president, vice-president, and ordinary member of council. Each time I have cancelled my nominations to the presidency, because it was obvious that some one else was desired, and I have always done my best to avoid a competition for the presidency, as tending, in my opinion, to compromise the dignity of the society. I have also cancelled nomination as ordinary member of council, because it seems to that election to such a position would not be sufficient evidence that the society wished me to again take an active part in its affairs, but I have allowed my nominations to a vice-presidency to stand. I trust that those who have nominated me during the last five years will consider this a satisfactory explanation of my conduct and accept my best thanks for their continued confidence.—Yours, etc.,

CHAPMAN JONES.

February, 1907.

### SULPHIDE TONING OF BROMIDE PRINTS.

To the Editors.

Gentlemen,—Under the above heading, "Dolphin" asks a question which no doubt interests a good many of your readers. Personally I have never been troubled with the particular difficulty which your correspondent raises, but I have experienced instances which were most perplexing of bromides which refused to bleach in the ferricyanide bath, or which bleached unevenly. After making many experiments to endeavour to fix the moment in the process at which the defect arises, my experience has been that sulphide toning always takes place regularly if development and fixation are quite normal. This is to say, that, given a correct exposure to suit a normal development and this followed by proper fixing, the sulphide toning will present no difficulties. That the ultimate colour obtained depends mainly upon the character of development, I think, is a statement of a generally observed fact, this also being in its turn influenced by the character of the deposit in the original negative; but toning to same colour always in my hands follows good dark-room practice.

In your reply you properly ask for further particulars of "development if aluminized or not, etc." It would be interesting to know if the cards were really bromide, as I have found some of the gaslight papers—presumably not coated with an "all bromide" or silver emulsion—work very differently compared to first-class makes of bromide paper. A bromide print, to tone well and to a good colour, especially if there be deep shadows, should be made upon a paper with a fairly heavy deposit of bromide and silver, and not too heavily coated with the gelatine vehicle. It may be that your correspondent has ventured upon the course of using a special chemical in bromide cards, the profits in such work, as he says, lean small; but, so far as one can judge from the particulars he gives, should be much more inclined to look, in the first instance, into the dark-room and ascertain if his dark-room arrangements for development and fixation were adequate, especially as he mentions that a large watch was being made.—Yours truly,

A. PROCTOR.  
[Our correspondent now writes that the prints were upon "Chessa bromide, developed with metol hydroquinone (Somerville formula) were aluminized (with two washes before and after), fixed for ten minutes, and washed for thirty-five minutes. The sulphide solution was freshly made. Not only did the cards refuse to darken in the sulphide, but the application of a developer failed to restore its intensity. The bleaching solution of ferricyanide and potassium bromide had been used only once or twice previously. We shall be glad to hear of other correspondents' experiences.—Eds. B.J.]

To the Editors.

Gentlemen,—In reference to the query of a correspondent last week as to bromide prints, bleached in the usual mixtures of ferricyanide and halide, which will not tone or darken in sodium sulphide solution. I have been experimenting with the process, and so far have been unable to succeed with this failure; that is, I have been unable to produce a print that will not darken in sulphide. May I take the liberty of asking any of your readers who have met with this may meet with this trouble, to kindly send me some prints or cards not more than six of each required, with full details, if possible, follows:—

Maker's name:  
Bromide or gaslight:  
Developer:

Plain or acid hypo:

Alumined or not:

Formula of bleach, and whether freshly mixed or not:

Formula of sulphide solution; also whether freshly mixed or not:

Whether prints were bleached in day or gaslight, or subsequently exposed to the same before sulphiding:

Length of washing after bleaching.

Some of these details may at first sight appear puerile and unnecessary, but as I have tried nearly every make of bromide and alight paper with ferrous oxalate, adurol and metol-hydro developers, without meeting with this failure, I want to obtain as many factors as possible so as to trace the cause of this particular trouble if I can.

I shall be pleased to pay postage on prints in all cases, and should I be able to find anything out will naturally communicate the same.—Yours faithfully,

E. J. WALL.

North View, Lansdowne Road, Sidcup.

#### PHOTOGRAPHIC PACKING PAPER.

To the Editors.

Gentlemen,—This heading called to mind a recent experience, and one in the last century. It has been often said that photographers are conservative. The following will prove the truth of that saying in regards trying every new plate or paper that comes along. A few years ago I received a sample of two half-plates made by the Beernaert company; like some others they were placed on a shelf in the dark-room, doubtless to wait for a convenient season. Clearing the shelf in November last they came to light with others. I was curious to see their appearance after so long. I found these were packed without dry paper between them while others had a fine tissue, the latter bore evident signs of deterioration from contact with the paper; the former (B.'s) looked in good condition.

Having many years ago proved to my own satisfaction, and then a well-known maker's fallacy of placing any paper in contact with the sensitive films, I felt a suitable occasion had now arisen to test the effect of plate-keeping without it, and so I copied a photograph I had to do on one of the two plates referred to, and another the same time on a perfectly new plate by a well-known firm. I sent one print from each, and shall be glad to hear your opinion of them. I did not know at the time that the Beernaert company had ceased to exist, and so for accuracy I wrote to Mr. Holzig, their agent, to ask whether he could furnish me with the date of the batch number. He then wrote me that the company had ceased to manufacture early in 1900; but for this fact I could have withheld the name lest it should appear I was advertising a certain make. It, however, was conclusive proof that they had not packed some years. I would emphasise: no paper between, or cards at edges, but film to film in close contact. I do not know why some firms will still persist in placing tissue between their plates; not only does it seem to me risky on the ground of deleterious matter in the paper, but it allows more air to pass between them, which has an injurious effect on the film, and in any change of temperature it also tends to the absorption of damp more or less equally. I can quite expect anyone saying we do not want to keep plates five or six years, and preferably not as many months, but the point is: Should not plates be packed in the way least likely to cause deterioration? It would be interesting to hear the experience of others on this.—Yours,

W. POUNCEY.

Dorchester, February 11, 1907.

[We do not think it would be possible to say without very careful examination, that the prints sent were from different negatives. With regard to the use of paper between sensitive films, it is possible to obtain a specially pure paper, known as the "Teapot" brand, made by Robert Fletcher and Sons, which is largely used by silver-plate makers for wrapping silver goods, and this has been proved to be without any effects on sensitive emulsions.—Ed. B.J.]

#### PYRO AND SODA DEVELOPER WHICH WILL KEEP.

To the Editors.

Gentlemen,—Your recent editorial notes and the articles and correspondence on this subject have called attention to a matter which is of very great interest to a large number of your readers. As one of your correspondents has aptly quoted, "An ounce of practice is worth a ton of theory," perhaps you will allow me to give the results of a few tons of practice, extending over a period of about fifteen years.

1st. As to keeping the pyro solution without deterioration, I have never been able to do this satisfactorily in combination with neutral or alkaline sulphite. The addition of a large excess of sulphurous acid (or metabisulphite) improves matters; but I have always found that in any case the solution deteriorates more or less rapidly from the time it is mixed. On the other hand, I find that metabisulphite of soda alone acts as a perfect preservative, a solution containing equal weights of pyro and metabisulphite appears to retain its good properties indefinitely; it will certainly keep in good condition for at least four years. After keeping two years or more, it works equally as well and as quickly as when freshly mixed. There is absolutely no difference in the results. If made with good and fresh pyro and distilled water the solution is quite colourless, and remains so to the last drop.

With regard to the alkaline part of the developer, I have never found any ill effects from mixing the sulphite and carbonate of soda in one solution. With equal parts of the two salts in a fairly concentrated solution it keeps perfectly, and, like the pyro solution, is always ready for use. I have tried various proportions, and for several years past have used the following, which I find excellent for all-round work:—

No. 1.	
Pyro .....	1 oz.
Metabisulphite of soda .....	1 oz.
Distilled water, to .....	80 ozs.
No. 2.	
Sulphite of soda .....	10 ozs.
Carbonate of soda .....	10 ozs.
Water (distilled), to .....	80 ozs.

For use, mix equal parts of No. 1 and No. 2. The mixed developer may be used full strength or diluted, according to the density required in the negative. For studio work it usually works best at about half strength. Development is complete at 65 deg. Fahr. in about five or six minutes. The addition of bromide increases contrast, but does not materially prolong the total time of development. There is no pyro stain. The negatives are neutral black in colour, and the solution may be used if desired for several plates in succession.

It will be seen that my experience coincides with that of Mr. H. W. Bennett, and is at variance with your own. The causes of the wide difference may not be far to seek, and, as you suggest that the manner of mixing may have something to do with it, I append a few details, in the hope that they may be of some help to you in solving the problem.

In the first place, all my solutions are made with cold distilled water. For the pyro solution the metabisulphite of soda in crystals (not powder) is completely dissolved in the water before the pyro is added; provided the pyro is not already spoiled by keeping, the solution will be quite colourless, and, as I have stated, it will keep so for years. In mixing the alkaline solution, the soda carbonate and the sulphite of soda in crystals are placed together in cold distilled water, and shaken until dissolved. This takes a little time, but I never use hot or warm water for dissolving the sulphite.

The above operations are so simple that it is difficult to see how one can go wrong; of course, it is essential that the sulphite be of good quality. I am inclined to think that herein lies the cause of most of the trouble. It is well known that different samples of sulphite vary considerably. I have met with some that were worse than useless. Also, I consider it essential to use pure water; a trace of iron would inevitably cause the pyro solution to become discoloured.

With regard to the metabisulphite, I do not know that there is any great difference between the potassium and the soda salt. I invariably use the latter, which I am in the habit of employing in the fixing bath, as it answers so well in the developer, and I do not see the use of mixing the bases. The chemistry is simpler by using the soda base all through. In connection with this there is one other point which may be worth notice. It will be seen that in my formula I have an excess of acid sulphite in the pyro solution, so that when the carbonate is added the free sulphurous acid is neutralised, and a corresponding quantity of freshly formed sulphite of soda is set free in the developer at the moment of mixing the two solutions. I feel sure that this has a beneficial effect. If so, it is entirely lost by the method of mixing the sulphite with the

pyro, as in your own formula. You will perhaps be able to test this in the course of your experiments, the result of which is no doubt awaited by many of your readers.—Yours, etc., B. J. EDWARDS.  
Ealing, February 9, 1907.

#### LIMELIGHT CALCULATIONS.

To the Editors.

Gentlemen,—Could you see your way to give a paper on limelight jets for the mixed gases, stating candle power obtained with a jet of a certain size when using a certain pressure measured in inches of water? For instance, assuming a thoroughly well-made jet, with a bore of, say, 20 standard wire gauge under a pressure of, say, 10 inches of water, what candle power can be obtained? Again, assuming the bore to be the same, but the pressure reduced to 5 inches of water or increased to 15 inches, what candle power would be obtained? Compressed gases in cylinders are out of the question here. Although I have read about Beard's and other regulators, I have never seen one, or have I ever seen it explained as to how many inches of water they are set to. This question of candle power of limelight jets seems to me too much rule of thumb. I cannot imagine why, with a certain size bore and with a certain pressure, one should not get a certain result. As a mechanic, I can tell the result of a flow of water and what effect to expect, provided I know the head, length of pipe, and size of jet, and also know how many candle power can be obtained from a Welsbach mantle burning under certain conditions, as tables have been laid down for these, then why not for the limelight burner, either blow-through, mixed, or ether? Any information on these subjects would be greatly appreciated by yours truly,

Bowmont Street, Invercargill, N.Z.  
December 3, 1906.

JAS. STEWART.

Mr. R. R. Beard, the well-known lantern expert, of Trafalgar Road, London, S.E., to whom we submitted our correspondent's letter, writes as follows:—

To the Editors.

Gentlemen,—Many papers have been written on limelight and tables prepared, but not in the form suggested in your correspondent's letter, and as regards candle power it must certainly be a case of rule of thumb, as so much depends upon the operator and the construction of the jets.

The suggested table of low pressure would be of no use under the present system of high pressure gases in cylinders as used here.

The outlet pressure of Beard's regulator can be modified by inserting springs of various intensities, from  $\frac{1}{4}$  lb. to 5 lb. per square inch in the ordinary form, and from the high pressure from 5 lbs. to 15 lbs. per square inch, the latter pressure being used with the injector form of jet.

With a jet constructed upon Hardwick's form—i.e., with a mixing chamber of about three-quarters of an inch diameter and 1½ in. long, and a pear-shaped vertical section, the gases entering at the base through a  $\frac{1}{8}$ th hole, and from the apex through the bent tube to the nipple, which is 18 gauge, and working the pressure of the gases at 10 inches, a Nottingham lime 3-16ths from the nipple will give, as near as possible, a candle power of 500.—Yours faithfully,

R. R. BEARD.

10, Trafalgar Road, Old Kent Road, London, S.E.

#### THE USE OF FLAMING ARC LAMPS IN PORTRAITURE.

To the Editors.

Gentlemen,—We have read Mr. A. Gascoigne's letter in your issue of February 1 with interest. As manufacturers of both flame arc lamps and enclosed arc lamps for photographic work, we may be able to supply some of the information Mr. Gascoigne desires. The colour of the flame arc is produced principally by the introduction of calcium and sodium salts. The spectrum of this light consists of a faint continuous spectrum on which are superimposed the very brilliant bands in the red, yellow, and green, characteristic of the calcium and sodium compounds, the visible spectrum being somewhat similar to the spectra given in your issue of January 11 on a Wratten plate without a filter, the extra amount of light in the yellow and green portions of the spectrum giving the arc its characteristic colour.

The spectrum of the Jandus enclosed photographic lamp shows a faint white light spectrum with intense bands extending over the violet and probably into the ultra-violet portion of the spectrum.

There is no definite ratio between the actinic and visual qualities of the two lamps, as by varying the proportions of the chemicals and the size of the carbons, etc., the light given by the lamps may be confined almost wholly to the yellow or violet portion of the spectrum as may be desired.

In an enclosed photographic lamp it is naturally important to confine the radiation as much as possible to that portion of the spectrum having great actinic value, nearly the whole of the energy being then available for photographic work.

We have used the term "photographic work" to indicate the effect of the actinic rays on photographic plates or papers. The usual term of "light" or "photographic light" is rather confusing, as the best forms of modern enclosed arc lamps can be arranged to give a large portion of their energy in the form of invisible radiations in the ultra-violet portion of the spectrum.

The following tests made in our laboratories may give some idea of the ratio of exposure. They are for four lamps, all taking the same electrical energy:—

	Visual Light, Giving Power Measured by Photometer.	Actinic Printing Power Measured by Darkening of P.O.P.
Jandus flame arc lamp .....	50	10
Open arc lamp .....	10	10
Ordinary enclosed arc .....	8	20
Jandus enclosed photographic lamp .....	4	50

These figures are approximations from the mean of a large number of tests. Variations in the current, varieties of plates and papers, and many other factors will influence results largely, but the figure are a guide for general use.

The relative actinic values will necessarily be altered very much if light filters are used, as these cut off a large quantity of the most actinic rays.

The results are fairly constant for printing work, and may easily be verified with a piece of P.O.P. by anyone who has access to both flame and enclosed photographic lamps.—Yours faithfully,

THE JANDUS ARC-LAMP AND ELECTRIC CO., LTD.  
(A. Denman Jones, works manager.)

Hartham Works, Hartham Road, Holloway, London, N.

#### PHOTOGRAPHS BY TELEGRAPH—A NAME FOR PROFESSOR KORN'S PROCESS.

To the Editors.

Gentlemen,—The general Press has during the past week devoted a good deal of space to descriptions of Professor Korn's process of photography by telegraph. Unfortunately, however, the word "telephotography" has been used to describe it, and although philosophically and scientifically correct, there is likely to be great confusion in terms if the use of this title is persisted in.

Since 1891, when the late T. R. Dallmeyer patented the first practical telephotographic lens, the word "telephotography" has been used by all our readers know, in every-day use to express the method of obtaining images on an enlarged scale by means of a lens which comprised an amplifying element in its construction and more particularly a lens composed of a positive and negative element, with a means for modifying the focal length by varying the separation. As there is already quite a literature on the subject, comprising volumes by Mr. T. R. Dallmeyer, Dr. Deller, Mr. Ernest Marriage, the Rev. F. C. Lambert, Mr. Beck, and others in all of which the word "telephotography" forms an important part of the title, we think it only fair that the newcomer should find a distinctive title in which, if possible, the electrical nature of the invention should be expressed. May we suggest "photo-telegraphy," which would clearly show that an actual telegraphic process was indicated. We have a precedent in "micro-photography" and "photo-micrography," the distinction between which is well known.—Yours faithfully,

J. H. DALLMEYER, LTD.

(C. F. Lan-Davis, secretary.)

Denzil Road, Neasden, London, N.W., February 12, 1907.

[Our objection to Messrs. Dallmeyer's suggestion is that, like "photo-micrography," it is a bad index word. Any person searching literature for Professor Korn's process will naturally turn first to "telegraph," and, therefore, a word commencing with "tele" or "tel" is, from an indexer's point of view, preferable to any other. "Electro-photography" or "telectrography," suggested in a previous issue, seems to us to meet the case, and we should not be surprised to see in future issues of "The Daily Mirror," when that publication

has completed its arrangements with Professor Korn, a page headed "Electrographs."—Eds. B.J.]

#### PHOTOGRAPHS BY AMERICAN PROFESSIONALS.

To the Editors.

Gentlemen,—Before the American Professional Exhibition at your gallery comes to a close, permit me this opportunity of counselling other professionals who have not yet seen it to take advantage of the remaining days, and your kind welcome. Many photographic exhibitions are interesting—this one is instructive also—and I think we have excellent reason to feel obliged to the exhibitors and the organisers of this little show for the pleasure it brings to professionals in this country. The work has the stamp of prosperity about it, and it is always a cheering thing to look at strong studio portraiture which one instinctively feels the public wants, and will pay for. We need not sympathise with the talk of decadence in British professional work, nor with the assertions of some critics who believe that artistic portraiture is only produced among clever amateurs here.

But this exhibition proves that the Americans represented are clever men and deserve all the prosperity which is said to prevail among them. Cannot we be up and doing to make another exhibition just as attractive for ourselves?—Yours faithfully,

Regent House, Anlaby Road, Hull. T. C. TURNER.

February 12, 1907.

## Answers to Correspondents.

- All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.
- For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

#### PHOTOGRAPHS REGISTERED:—

- Miss E. Hargreaves, Millom, Cumberland. Photograph of the Rev. F. Pascoe.
- H. Midwinter, 48, Park Street, Bristol. Three Photographs of Blind Child Vocalist, Eva Lombottom.
- J. C. Long, 22, Portland Road, Worthing. Four Photographs of Interior of St. Andrew's Church, Worthing.
- Mac Perkoff, 186, Commercial Road, London, E. Photograph of Mr. Z. Feinman, Famous Jewish Actor.

- Treanor, 21, Inglis Street, Inverness. Photograph of the Rev. M. MacKenzie.
- Photograph of the Rev. J. J. Black, L.L.D.
- Burton and J. W. Burton, 3, Haymarket, Leicester. Photograph of Sir A. Hazerigg, Bart.

H. (Nottingham).—The apertures of lenses do not necessarily vary with the size of the stop. With two lenses of 16in. and 14in. focal length the apertures may be of the same and the stops of different sizes, or vice versa. All depends on the front lens of the combination. You should measure and compare the "effective apertures," as defined by the R.P.S.

MS QUERY.—I have an old lens by Dallmeyer, marked on mount No. 1a, Patent 9669. The lens mount is 1½in. diameter, about 2in. long, single combination in back and front, small rotating stops. Can you identify it for me? The back combination appears to be incomplete. There is a little cell which fits close to the front of lens, from which it appears to me there is a lens missing. I find on focussing I get on the ground glass a white flare spot in the centre of the picture, just about the size of a stop or a little larger. Is that caused by the front lens being missing? Can you tell me what focus the lens should be, and rapidly?—A. J. F. BOND.

The lens, by its number, is of very old make. Your description answers to that given in an old catalogue we have, of the No. 1A patent wide angle landscape lens, and is intended for 5 x 4 pictures. It is a single combination, and of 5½ inches focus. Its aperture, we think, is about f/15. If you send the lens to Dallmeyer's they will tell you whether it is complete or not, and for what work it is intended.

BACKGROUND MATERIAL.—I should be glad if you could inform me where I can obtain canvas for background painting in distemper.

—ARTIST.

Unbleached sheeting, obtainable from large upholstery warehouses, up to 8ft. and more in width.

PROFESSIONAL.—So long as the prints are kept separate and constantly exposed to clean water, a mechanical washer is superior to hand washing, supposing also that it does not tear the prints. For prints of fairly small size, up to half-plate, there are several washers—e.g., the "Godstone," the "V.H.," which will be satisfactory, but we know of no washer which will satisfactorily treat numbers of large prints. The principle of one made by Messrs. Marion, in which each print is kept in a separate tray, is the best.

PHOTOGRAPHS ON METAL.—(1) You were kind enough to answer an inquiry of mine some few weeks back re "Carbon Transfer on Metals." I find, on following your instructions, the adhesive preparation you advise (chrome alum and gelatine), will not give it a hard support, as on passing a shears through the metal the tissue is liable to strip. I tried Japan varnish, but that seems only to prevent moisture attacking it. Can you suggest another method. (2) Stoving it. How should I proceed? (3) Is there any book that would give me the method of working ceramics—the full details?—F. R. O.

(1) The trouble, no doubt, arises from the metal not being thoroughly clean in the first instance. The slightest trace of grease would quite prevent the adhesion of the substratum to the metal. If the metal is highly polished we should suggest that you slightly dull it by immersing it for a minute or so in water to which a little nitric acid is added, just sufficient to give it a sour taste. That will afford a better tooth for the substratum.

(2) Without suitable appliances you are not likely to be successful with this. We should advise you to put the work in the hands of a practical japanner, who will have suitable ovens for the purpose. (3) "Photo Ceramics," by Ethelbert Henry and Snowden Ward, 1s. Dawbarn and Ward, 6, Farringdon Avenue, E.C.

A. K.—(1) The rough sketch shows quite a different thing from Adamson's compressor, though we do not see why it should not answer your purpose. Personally, we have had no experience in making compressors, and therefore can express no decided opinion on the merits of the one you propose to construct. Indeed, its efficiency can only be proved by a practical trial. (2) To speak candidly, we cannot congratulate you on either the lighting or posing of the specimens you submit. They are all illumined too much with direct front light. (3) No. 2 of the "Photo Miniature" (Dawbarn and Ward, 6, Farringdon Avenue, E.C. 6d.).

FINGER PRINTS.—Do you know of a book on finger-print photography, same method as used by the police? If so, would you inform me where I could obtain a copy? If no book published, what is the best method to get a negative from a faint impression?—THE MB-NAIL.

There is no work published on the subject. If the finger prints you have to photograph are on paper, copy them in the camera in the ordinary way. If they are on glass they will yield a better result by being copied by transmitted light. For the negatives use slow plates, giving good density—e.g., a photo-mechanical plate.

"VENUS" TONING BATH. — I should esteem it a favour if you could give me the Venus toner for P.O.P. I have written to the firm who used to manufacture that brand of P.O.P., but letter has been returned, marked "Gone away."—W. BRISTOW.

Potass. chloroplatinate .....	2 grs.
Sodium chloride (common salt) .....	30 grs.
Citric acid .....	30 grs.
Distilled water .....	20 ozs.

The above (1900) is the latest formula we have been able to turn up. We may add that Messrs. Burroughs and Wellcome sell a tabloid chemical made up for the "Venus" paper.

RECOVERY OF DEBT.—I made an oil painting for a customer, from a copy he gave me. The eyes were not exactly the same size on the copy. I made it according to the copy. He would not have it, because one eye was smaller than the other. He asked me

to alter it. It has been altered. Now he will not have it at all. Can I make him pay for it, and in what way?—W. H. R.

If the enlargement in the first instance was like the original it ought to have been satisfactory. If it was afterwards altered to your customer's order, you are not responsible for that. As a rule when alterations, such as this, are made from the original the result is seldom satisfactory. The only way to recover the debt is to sue for it in the County Court.

**FLASH POWDER.**—Please publish a reliable formula for flash powder in your next issue.—REX.

Potass. nitrate .....	12 parts.
Potass. perchlorate .....	12 parts.
Magnesium powder .....	16 parts.

We advise you to employ the ready-made powders, as the mixture of the constituents is a rather dangerous operation.

**YACHT PHOTOGRAPHY.**—(1) I have been located in this place nearly four years, and I am not satisfied with the amount of work I have obtained from the yachting people. I have taken several fairly decent pictures of yachts sailing, with the ordinary T.-P. shutter, but the results are very uncertain. Now, could you tell me of any special apparatus? (2) I am adapting a half-plate camera for instantaneous work by attaching a focal-plane shutter. Will you please tell me what is the best view-finder of reasonable price to use?—C. T. HUMPHREY.

A twin lens or reflector camera is used a great deal for this class of work. We knew one very successful photographer of yachting subjects who had a miniature camera, about 5 x 4, fitted to his 15 x 12 camera, the focusing gears of the two being arranged so that the subject was focussed in the smaller by moving the pinion of the larger camera. This is simply the twin-lens system modified to reduce bulk. The exposures are usually 1-200th to 1-500th of a second—i.e., with a focal-plane shutter. We may add that successful yacht photography involves a steam or motor launch, in which to follow the craft and catch them at the required angle. You will find some most useful hints on the subject in "Photography on Tour" (Dawbarn and Ward, 1s.). (2) Our own preference is for one of the direct vision type of a good size, say, with a lens 2½ x 2 inches. The cost is about 10s.

**IODIDE FOCUSING SCREENS.**—On page 713, of your "Photographic Almanac," 1907, you give instructions for making focussing screens with iodine or potassium iodide. Will you please inform me in your journal the amounts of iodine and potassium iodide to use?—J. HARTLEY ELLIS.

The exact strength is not of importance. You can use one containing about 10 grains of iodine and 100 grains of potassium iodide in 10 ozs. of water.

**PHOTOGRAPHS OF FLOWERS AND ANIMALS.**—Herewith I beg to ask you whether you can give me some addresses of flower and animal photographers.—F. O. KOCH.

For flowers try: Erdman and Schanz, 109, Bedford Hill, Balham, London, S.W.; Valentine and Sons, 32, Charing Cross, London, W.C.; Henry Irving, The Rowans, Great Elms Road, Bromley, Kent; Taunt and Co., Oxford; Colonel Taylor, St. Agnes, Cobham Road, Norbiton, Surrey; Charles Hodges, Hexham Northumberland; T. Andrews, 15, High Street, Budleigh Salterton; W. W. Burnard, West Street, Poole, Dorset. For animals: Chas. Reid, Wishaw, N.B.; G. W. Wilson and Co., 2, St. Swithin Street, Aberdeen; O. G. Pike, The Elms, Winchmore Hill, London, N.; Jas. Auld, Ellon, N.B.; and Gambier Bolton, care of Autotype Company, 74 New Oxford Street, W.C.

**"IRIS" MOUNTS.**—Will you please give me the address of the makers of the "Iris" mounts series?—GEO. WOOD.

We see the mounts listed on page 666 of Fallowfield's catalogue, but we do not know the makers. We shall be glad to hear from you on the other matter.

**COPYRIGHT.**—I produced a series of local views of Fishponds and district for postcards. I supplied local stationers with them. Finding the profits so small with this kind of work I discontinued to supply them, and intended to sell them at my own shop at 2d. each. It has just come under my notice that a local company has copied my photographs, imitating photographic cards, and selling them at 2d. each. Every imitation card bears my

name, saying it is a photograph by me. What can I do in this matter? It is affecting my retail sale.—C. F. B.

You cannot take action in respect of infringement prior to registration of the copyright in your photographs. Apparently you have not registered any. You had better do so at once, and you can then stop the sale of further copies.

T. W. S.—Try the Tress Company, or the Halifax Photographic Company.

A **CONSTANT READER.**—1. The card is probably a matt surface bromide, and any make would give you similar results to the which you enclose. A good developer is:—

Metal .....	35 grs.
Hydroquinone .....	50 grs.
Sodium sulphite .....	2 ozs.
Sodium carbonate .....	14 ozs.
Water to .....	20 ozs.
Potassium bromide .....	5 grs.

2. With regard to the bleaching solution, if you use that given on p. 988 of the ALMANAC, 1907, you cannot fail to get good results. You can also use the one you enclose, but it will, of course, intensify the prints.

**ENLARGING LENS.**—I have a lantern which I bought second-hand and wish to use it for enlarging. When I got it home I found the original back lens had been replaced by, it seems to me, one from a pair of field glasses. I have tried to use it, but can only get the subject in focus at a distance of about 18 inches from the lens. It was then not very sharp, so I made a stop to fit in front of lens, and have got a passable picture with it. I would like to know if the combination of the lens is right. The lens is composed of two plano-convex lenses. Diameter of front lens 40 m/m, and back one 44 m/m. The diopter of front lens is 5.2 and back one 5.75. The distance from back lens to negative when lens is fully extended is 115 m/m. The distance between the lenses is 60 m/m. If you can give me the information from the above description I shall be glad. The stop I used fixed on the front of cap of lens, and the aperture is 11 m/m.

If your lens consists only of two plano-convex lenses it is no use for enlarging. Are you sure they are not cemented combinations? In any case, the stop should be between them, not in front. If a central stop and properly adjusted light will not give good focus the lens is useless, and you had better replace it by your camera lens. That should work satisfactorily. Remember that adjustment of light affects focus, and that adjustment must be varied for different scales of enlargement.

A. B. (Bagshot).—1. Rubber type can be purchased from M. Lindner, Fleet House, Farringdon Avenue, E.C. The neatest way, however, to title postcards is to obtain the lettering in the negative by photographing a proof of the title, stripping the film, and transferring to the postcard negative. 2. "A Treatise on Photogravure," by Herbert Denison (London: Iliffe and Co., 4s. 6d.).

R. M. CLIFFORD.—It can if provided with the usual focussing scale. As the camera has to be held about at the chest level, a reflex finder is the most suitable. Adams and Co., Charing Cross Road, W.C., can offer you a variety.

H. HOPPERTON.—You had better send it to be repolished. We do not suggest no other plan.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The exhibition of photographs by American professional photographers at the "E.J." offices) closes to-morrow, Saturday, at 2.30 o'clock.

Workmen's compensation and photographers. We draw attention to the terms of the Act which comes into force on July 1. (P. 135.)

A revised draft of the proposed Copyright Bill shows the Artistic Copyright Society to be still disregarding the interests of photographers. (P. 134.)

Note-paper with half-tone illustrations is recommended as a possible sideline for photographers. (P. 133.)

American photo-engravers' business methods and book-plates as a possible side-line occur in "Photo-Mechanical Notes." (P. 144.)

A review of modern mounting methods by Mr. Hector Maclean appears on page 141.

Experiments on the latent image have led unmistakably to a new process for red and blue tones on bromide paper. (P. 136.)

MM. Lumière and Seyewetz, as a result of testing the exhaustion of fixing baths, have drawn up rules for the maximum number of plates to be fixed in a bath of given formula. (P. 138.)

New hints on the ozobrome process appear in the new issue of the official instructions. (P. 140.)

The catatype process of chemical printing (without light) has been demonstrated in Berlin. (Pp. 134 and 143.)

Pigmented bromide paper for the direct production of carbon engagements is the subject of some notes by a German writer. (P. 139.)

A non-splash dish is among the patents of the week. (P. 145.)

Society proceedings of the week deal with shutters, stereoscopic photography, and wet-collodion lantern-slides. (P. 148.)

## EX CATHEDRA.

### Half-tones on Note-paper.

Only a little time ago we commented on the business to be done by a studio in the supply of note-paper bearing a heading of a photographic nature. The idea is quite an old one, of course, but with the increased interest, amounting almost to a craze, in all kinds of pictures, photographers who may have dismissed the proposition years ago as having nothing in it may find to day that it will pay them to take it up. Among all classes of their customers—the dweller in a country house, as well as the mother of a pretty child—there is the opportunity to put forward the illustrated note-paper as a novel specialty of one's own, and it will be found that not only in the upper social strata of a provincial public, will it be the means of putting money into the photographer's pocket. One point of practical importance may be mentioned. It will be found that many papers which will take a pen properly will not do justice to the half-tone block. A paper possessing both qualifications is not easy to find, and therefore we may mention a new introduction of Messrs. Lindenmeyr's, the "half-tone writing paper," which should be noted by those entertaining our suggestion for application to their own businesses, or, as one or two firms might well do, by those proposing to supply and print the blocks for the photographic profession.

\* \* \*

### Libel or Criticism?

Colour photography of all subjects has been disturbing the law courts of far Singapore, where a firm of photographers have sued the proprietor of a newspaper in respect of a letter appearing in his publication in which adverse reflections were made upon certain specimens of colour photography, shown by the plaintiffs at an exhibition, and also upon the character of the plaintiff's representative. The letter in question was headed "A Dismal Failure," and in it the writer commented upon the imperfections of what we gather to be three-colour carbon prints. These remarks, however, the Chief Justice held to be no libel, but in respect of the allegation as to the character of the plaintiff's representative gave judgment for £20 and costs.

\* \* \*

### The Pyro-Soda Developer.

We are much indebted to Mr. B. J. Edwards for his letter on page 129, and for his valuable suggestions. Our correspondents seem to be about equally divided in their opinions and experiences, which fact alone makes it clear that there is something that we do not generally understand with regard to the compounding of developers. Mr. Edwards says, "Of course, it is essential that the sulphite be of good quality. I am inclined to think that herein lies the cause of most of the trouble." Mr. Edwards uses more sulphite than we do in proportion to the pyro, and if he also uses

a better quality he must have a considerable excess of pure sulphite available. In this case a formula that is compounded on incorrect principles may quite easily work in as cleanly a fashion as one correctly compounded with less sulphite. Though at present we have nothing fresh in the way of information to give, our earlier work showed pretty clearly that the quantity of sulphite could be considerably reduced if it was not kept in solution with the alkali. If the alkali and sulphite were combined, then, with the sulphite we used, stain could not be avoided unless an inconveniently large quantity was employed. The moral appears to be that if one wants the sulphite and alkali to be together, one must use plenty of sulphite of exceptional purity. If, however, one can make a smaller quantity of a cheaper quality serve equally well it appears to us that a considerable advantage is secured.

#### The Hydroquinone Developer.

We have been conducting some parallel experiments with the hydroquinone and caustic soda developer with almost exactly similar results. We found that a formula in very general use, in which the caustic soda and sulphite are dissolved together while the hydroquinone is preserved with metabisulphite, had a useful life of less than three months. It began to work slowly and to give stain after about two months. The sulphite in the alkali solution lost its stain-preventing properties, the alkali deteriorated, and the hydroquinone solution became coloured. A fresh alkali and sulphite solution then remedied matters, but before very long the hydroquinone solution became so deeply coloured and lost so much power as to be useless. We transferred the sulphite to the hydroquinone bottle and modified the formula slightly, the result being a solution that keeps water-white for many months. The caustic soda solution, of course, still deteriorates, and must be occasionally re-made; but otherwise the developer keeps perfectly. It, however, has precisely the same peculiarity as the pyro-soda formula we gave some time ago, in that it works very much more slowly than the old formula at its best. The time of development has to be doubled, and the cause of this effect of restraint is as much a mystery as it is in the case of the pyro-soda developer. A curious feature of hydroquinone is that there is generally a little uncertainty as to what the hydroquinone solution is going to do. Old and well-tried formula sometimes give a solution that turns nearly black in a few days, though in the ordinary way they keep fairly well.

#### Catatype Printing.

If we may judge from the report of a lecture given before a Berlin photographic society, the method of chemical contact printing, invented by Professor Oswald and Dr. Gros some four years ago, has been brought to a practicable commercial stage. In the hands of the Neue Photographische Gesellschaft it has been developed from the laboratory stage to which its inventors brought it, and has now approached the point at which it may be turned over to persons who do not possess the chemical skill of a University professor. We gather that the bromide negative from which the copy is taken by contact only, without exposure to light, has to be on a special paper, and to have special solutions for its development and fixation. From this negative, contact of about two minutes' duration serves to impress on the catatype paper an invisible image formed in hydrogen peroxide, with which substance, in a special form of solution, the negative is saturated. A brown image, convertible into others of different colours, is produced by treating the latent image with a manganate solution, or, as an alternative, the peroxide representing the print may be employed to impart insolubility to bichromated gelatine,

and thus be the medium for the making of a pigment print. We shall await with interest the appearance of this process upon the British market. It is sufficiently different from the now popular ozobrome process of "lightless printing" to create as much interest as the latter, though it can hardly hope to exceed the directness and beauty of Mr. Manly's method.

#### A Colour Process.

We should like to know more of Professor Francis Lyonde, "the eminent French Photographer," who we see has so far descended from his eminence to allow a firm in the United States to sell directions and materials of a process for producing a photograph in colours. From the advertisement of the firm, the Buffalo Distributing Agency, of 17½, East Swan Street, Buffalo, we learn that they are "now able to offer to those desiring to learn the art, full instructions, including material, set of samples, etc., for the nominal price \$5.00." We do not profess any knowledge of the advertiser's process, yet we are of the opinion that twenty shillings is a good deal of money for the materials offered, in view of the fact that "Professor Lyonde's" reputation as a photographer appears to be considerably less in London than it is stated to be in Buffalo, U.S.A.

#### Proposed Changes in Copyright Law.

The deliberations of the Artistic Copyright Society, which for some years past has had in hand the drafting of a Bill amending the present law of copyright, have lately resulted in a revision of the draft which was published in our issue of January 19 last year, and in regard to which we could take no other course than to point out its many inconsistencies, and its inequity in legislating for one class at the expense of another. The later draft is more comprehensible, but no less unjust to photographers. The most obvious alteration is the removal of Clause 7 from the previous issue and the insertion of a clause in Part II. which still more favours the publisher at the expense of the illustrator. We had better place the two side by side:—

Removed January, 1906.

In the case of an artist sending a sketch or drawing to an editor for publication the act of sending this sketch or drawing and its acceptance and payment therefor is to be taken as conveying the copyright from the artist to the proprietor of the publication.

Inserted January, 1907.

If the author shall send his sketch, drawing, or photograph to an editor or publisher of any publication unaccompanied by any prohibition or restriction against the reproduction thereof or by any indication that he does not intend the work to be reproduced without further negotiation, the reproduction thereof by such editor or publisher in his publication shall not be deemed any infringement of copyright of such author or his assigns in such sketch, drawing, or photograph. If no price be named by the author for the use of the sketch, drawing, or photograph, the author or his assigns shall be paid by the user according to the scale of payment of the publication for such work.

We cannot interpret this clause as anything else than the legalisation of piracy on the part of producers of illustrated journals. For what—do the framers of the Bill imagine?—does a man send sketches or photographs to a journal but to sell a limited right to reproduce? This clause makes the title of the Bill, "The Consolidation and Amendment of the Law of Copyright," a distinctly humorous phrase. No alteration from the previous draft is observable respecting the marking of prints necessary to sustain copyright in photographs and in copies of works of fine art. The proposition that any person coming into possession of a copyright photograph not so marked is there-

exempt from action for infringing it, obviously opens the door to all manner of piracy; and, as shown by the working of the same provision in America, virtually destroys the photographer's copyright in his productions.

#### Poison Statistics.

The returns of the Registrar General in reference to deaths by poison in the year 1905 cast some interesting light on the difficulties which attend the restriction in the facilities for obtaining poisonous substances. The scheduling of tartar emetic, anhydrous ergot of rye, and savin has doubtless been the cause of the total absence of these drugs from the list of fatalities, but, on the other hand, carbolic acid has been scarcely affected by the scheduling of it in 1900. Out of 10 deaths, a total of 379 are due to mineral acids, oxalic acid, carbolic acid, and potassium cyanide, a fact which shows the inefficacy of scheduling as a means of preventing poisons from coming into the hands of would-be suicides.

#### Chlorate or Flashlight Powders.

A note by Dr. R. Gartenmeister in the "Chemiker Zeitung" draws attention to a point in the chemical control of mixtures of chlorate and combustible bodies which may well be recorded for the benefit of those employing the former substance in the manufacture of flashlight powders. In the case of several explosive mixtures where the explosion had taken place spontaneously, it was found that the chlorate which entered into the composition probably contained hypo-chlorite or some other lower compound of chlorine, capable of easily disengaging a lower oxide of chlorine. The presence of this impurity was found by adding to the cold solution of the chlorate a little solution of starch and potassium iodide. The iodine liberated by the oxide of chlorine showed its presence by the immediate darkening of the starch from the formation of iodide of starch. A faint reaction of the same kind was observable in other samples of chlorate in which there was no complaint, but the phenomenon was probably due to the presence of traces of iodic acid in the potassium iodide used for the test. The behaviour of the chlorate does not seem to be absolutely identified with its response to this iodide test, but the latter may nevertheless be borne in mind by those who have occasion, as in flashlight powder manufacture, where the conditions are most of the same, to employ the substance in admixture with a combustible body.

#### PHOTOGRAPHERS AND THE WORKMEN'S COMPENSATION ACT, 1906.

On July 1 of this year the Workmen's Compensation Act, 1906, becomes operative, and the changes which it will involve are of such a serious nature that it is essential for every employer to consider his position. Whether the legislators who are responsible for the same actually realised the effects of the Act may be left an open question. We need not discuss that, but attempt to point out some of the possible results.

By this Act the word "workman" is defined in the most general sense; liberal, not in its political significance, but as inclusive of anyone who works. It includes all employees of every description, whether clerks, domestic servants, commercial travellers, shop assistants, tutors, verners, etc., who may have entered into a contract of service or apprenticeship with an employer, whether orally or in writing, provided that the remuneration does not exceed £250 per annum. It includes also those who may only work part time, that is to say, an employee who may divide his time between two employers is by this Act a workman of both. Those who are not included in

the benefits of the Act are such as are casually employed and those who are employed otherwise than for the employer's trade or business. Exactly what the meaning of this is cannot now be stated. It may apply to charwomen, window cleaners, and so on, but until two or three actions have been fought and rulings given on this point it is a dubious one. Out-workers, that is, persons to whom work may be given to do, finish, or ornament at home cannot claim, when the work is done on premises which are not under the control of the person who gives out the materials, etc. Neither can any relative of an employer, if living in his house, claim compensation.

From the above will be seen how extremely comprehensive the Act is, and also, from what follows, that compensation has to be paid, not only to an injured employee, but in the case of death to the deceased's dependants.

An employer is liable for compensation for personal injury caused by accident arising out of or in the course of the employment. But he is not liable unless the employee is disabled from earning full wages for at least one week. Nor is the employer liable if the injury is caused by serious and wilful misconduct on the part of the employee, unless it results in death or total disablement. Should the injury be caused by the wilful act or personal negligence of an employer or of a person, such as a manager, for whom he is responsible, then the employee may claim under this Act or proceed independently. Under the Act the compensation is limited; otherwise it is not.

When an accident occurs notice must be served upon the employer as soon as possible, and claims for compensation must be made within six months of the accident or death.

If the employee leaves dependants the compensation payable if they are wholly dependent on the deceased's earnings shall be calculated on the previous three years' earnings of the deceased, or if the latter had not been for three years in the employer's service at the time of his death, then it shall be one hundred and fifty-six times the average weekly earnings, provided only that the sum shall not exceed £300 nor be less than £150. Partial dependants are to be compensated by a reasonable sum proportionate to the dependant's loss. Should there be no dependants then all reasonable expenses of medical attendance and burial not exceeding £10 must be paid.

"Dependants" is again most liberally defined by this Act. It includes wife or husband, father, mother, grandfather, grandmother, stepfather, stepmother, son, daughter, grandson, granddaughter, stepson, stepdaughter, brother, sister, half-brother, half-sister, or illegitimate children, and it also applies to the parent or grandparent of an illegitimate child.

Total or partial incapacity is to be compensated by weekly payments not exceeding one-half the employee's average wages during the previous twelve months, if he has been that time in the employer's service, or if not, for the time that he has been in his service. The weekly compensation must not exceed £1. Should the incapacity last less than two weeks, no compensation need be paid for the first week. A minor is entitled to the whole of his average weekly earnings, but the weekly payment need not exceed 10s.

The amount earned by an employee is the total amount of his wages for the previous twelve months; but when he has not been in one employ for twelve months, or if he has been only in casual employ, or it is impracticable for any other reason to ascertain his average weekly earnings, then those of another employee of the same grade, either in the particular employer's service, or the earnings of a person in the same grade employed in the same work in the same district shall be taken as the basis of the award.

Further, if an employee has been but a short time in the service of an employer then his average earnings under previous service shall be considered.

An employee working for two firms can claim from either, as compensation for injury, half his total wages. For instance, A works for B from 9 a.m. to 5 p.m. and receives £2 per week; from 6 p.m. to 10 p.m. he works for C and receives 15s. per week; if then he receives an injury whilst working for C, the amount of compensation shall be  $40s. + 15s. \div 2 = 27s. 6d.$ , which he can claim from C.

Any contract or understanding, written or unwritten, between employer and employee to the effect that the latter shall not be entitled to the benefit of the Act is contrary to law and void. This obviously is aimed at an employer who might, when an action or claim was made against him by a deceased employee's dependants, produce a written agreement to prove that the deceased contracted out of the Act.

Should any person undertake a contract for work and lease it out to another person and an accident occur to the latter's employee, then the first person is liable to claim for compensation. As an example, let us take the case of a firm of photographers, X., who undertake a contract for doing the whole of the photographic work of a large engineering firm in London, for instance, and in the course of that contract are required to obtain a photograph of some particular subject at Edinburgh. By the terms of the contract it would not pay X. to send an operator specially to Edinburgh, so they employ a local photographer, Y., to do the work. Y. sends an operator who is injured, then the claim for compensation can be made against X., and the only satisfaction that he has is that he may claim indemnification from Y. The employee can claim against either X. or Y., not from both, and supposing that X. is a wealthy man, and Y. but a man of straw, there is not much doubt

as to what would happen, and in either case X. is in an unhappy position.

Should an accident happen to an employee through the wilful neglect or carelessness of a third party, who is not the employer, then the claim would lie against this third party, and the employer can claim indemnification from him. This obviously means that if a photographer sent an operator to take a photograph at a third person's premises and the operator was killed or injured through the wilful neglect or carelessness of this third party, then the latter is liable to pay compensation, but not both compensation and damages.

Any weekly payment arising under this Act may be reconsidered and ended, diminished, or increased on application by either party, and such weekly payment may be compounded by payment of a lump sum, which shall be sufficient to purchase an annuity from the National Debt Commissioners, through the Post Office Savings Bank equal to three-fourths of the annual value of the weekly payments. So thoroughly have the legislators responsible for this Act safeguarded this compensation, that it is impossible to assign, attach, or charge it, neither can it pass to any other person, nor can any charge be set against it.

We have not thought it necessary to deal with the methods of recovering compensation, although these would be, of course, of considerable interest to the very large body of employees of all classes who are readers of our paper. We trust, however, that we have said enough to convince every employer that it is at once his bounden duty to immediately insure himself against all possible claims under this Act. Many insurance offices have already fixed their tariff of premiums, and for the sake of the few shilling required it is not worth while risking a possible claim which may hang for years round the neck or lead to a serious drain on one's resources.

## EXPERIMENTS ON THE NATURE OF THE LATENT IMAGE AND OF THE NEGATIVE IMAGE.

THE following article from "Photographische Korrespondenz" supplies an addition to the proofs of the compound nature of the latent image. Incidentally, Dr. Homolka's experiments (permanent indigo compounds) on bromide paper.

DURING the last two decades various theories have been advanced as to the nature of the latent image; they may, however, be arranged in two groups: (1) Those which ascribe the formation of the latent image to a chemical change in the silver bromide molecule during exposure—the sub-halide and silver grain theory; and (2) those who deny any chemical change, and assume a structural alteration structure theory, photo-electric ionisation without reduction, etc. Each view has doubtless much to recommend it; neither appears to me to be convincing.

The present state of our knowledge as to the nature of the developed negative image is, however, much clearer, and Lippocramer has proved that the developed negative image is not of a homogeneous nature, but composed of two substances, of which one is most probably metallic silver, the other probably a silver compound.<sup>1</sup>

As regards the chemical development of the latent image with organic developers, Eder says:<sup>2</sup> "The 'chemical' development is characterised by a reduction process, in which exposed silver halide is converted into metallic silver; the unexposed

is, however, left intact. The number of organic compounds which possess this action is doubtless very considerable. . . .

This extract is important as regards the view which generally exists to-day as to the chemical development of the latent image into a negative. It is assumed that only certain organic compounds of special constitution are capable of reducing the latent image to a visible negative, relatively that the substance of the latent image can only exert an oxidising action on the compounds. The question whether the substance of the latent image is an oxidiser in the wider sense of the word, that is to say, whether it can oxidise not only the so-called developers but also other organic compounds, has, according to my thinking, never yet been investigated, although the answer would doubtless be of considerable importance, not only to the theory of the latent image, but also for that of the negative image. I have therefore approached this question from the experimental side.

Organic chemistry of the present day gives us numerous compounds which are more or less easily oxidised; yet the great assortment is considerably narrowed down by certain requirements which must be given to those compounds chosen for the work in question. The product of oxidation must first be chosen so that it—especially under the peculiarly difficult

<sup>1</sup> Phot. Korr., 1905, p. 319.

<sup>2</sup> Handbuch der Photographie, 5th edit., Vol. III, p. 289.

perimental conditions—can be easily and certainly observed ;  
at is to say, it must be coloured. There are a great number  
organic compounds, themselves colourless or nearly so, which  
re strikingly coloured oxidation products. Notable are the  
called leuco-bases of the diphenylmethane, triphenylmethane,  
diphenylamine series, which, by oxidation, are converted  
to the well-known brilliant aniline dyes. Simple con-  
sideration of these will at once teach us that they are unsuitable  
for exact experiments in the desired direction ; they all contain  
one or more amino or oxy groups, or the two together, in  
combination with aromatic benzene nuclei, and may therefore  
be suspected of being capable of acting as photographic  
"developers" in the usual sense. In the case of a few—e.g.,  
leucindamine and leucoindophenole—ordinary developing  
experiments can be proved without difficulty. The use of these  
substances might, therefore, easily lead to fallacious conclu-  
sions. Finally, it is desirable, if not absolutely essential, that  
the coloured oxidation product of the substance used should  
be insoluble in water, and, therefore, remain at the place  
of its formation ; in any case, the observations would be made  
much easier by this property.

With these facts in view, I have examined a great number  
of organic compounds as to their behaviour towards the latent  
image, and finally found two which satisfy the stated require-  
ments. These are indoxyl and thioindoxyl ; the latter is closely  
related to the former in chemical behaviour.

Indoxyl, which is the intermediate product in the production  
of indigo from indol, exists in two forms—in the normal form  
β-indoxyl, and in the so-called ketonic or pseudo-form :

It dissolves freely in water with a faint yellowish colour and  
greenish fluorescence, and this solution is completely and  
instantaneously oxidised to indigo by the very mildest oxidiser,  
according to the equation :

The so-called thioindoxyl :

The pseudo-form, is slightly soluble in water, but dissolves easily

in dilute alkalis. In these solutions it is converted by oxidis-  
ing agents into red thio-indigo, according to the equation :

Experiments have now proved that indoxyl, as well as thio-  
indoxyl, is oxidised by the substance of the latent image or  
a certain part of the same, to the corresponding indigo dyes.

Before any theoretical importance is attributed to this fact,  
one must try whether the two indoxyls cannot act as developers  
in the ordinary sense. This question can be definitely denied  
according to the present state of our knowledge of the con-  
nection between chemical constitution and developing power.  
At any rate, one might imagine that indoxyl had developing  
properties, for one can imagine—at least, for the meantime,  
only on paper—that it could be split up into a methyl-o-amino  
benzyl alcohol :

which could always act as a developer. The simple o-amino-  
benzyl alcohol :

possesses, as I have proved experimentally, no developing  
power ; therefore, such is not to be expected with methyl-o-  
aminobenzyl alcohol. The behaviour with thio-indoxyl is much  
more favourable ; this can—also only on paper—be thought to be  
resolved into the following substance :

which lacks every sign of a developer.

The latent images necessary for this experiment were obtained  
by exposing gelatino-bromide plates with 3 per cent. of silver  
iodide, behind a Chapman-Jones photometer scale to a standard  
candle at 305 mm. distance for thirty seconds. After develop-  
ment with amidol, the plates showed a sensitiveness of 22 deg.,  
corresponding to 12 deg. Scheiner.

**The Action of Indoxyl and Thio-indoxyl on the Latent Image.**

If an exposed plate is placed in about a 2 per cent. aqueous  
solution of indoxyl, a visible image appears. An addition  
of sodium sulphite to the developer accelerates development ;  
potassium bromide, even when added in considerable quantities,

does not slow it, and keeps the plates very clean. The following developer is therefore recommended:—

Sodium sulphite, 6 per cent. sol. ....	100 ccs.
Potassium bromide .....	5 gms.
Indoxyl .....	15-20 gms.
Water .....	1000 ccs.

In this the plate will be thoroughly developed in from five to eight minutes; it should then be rinsed with water and fixed in the ordinary way in an acid fixing bath.

The same phenomena appear if thio-indoxyl is used instead of indoxyl.

The following developer should be used:—

Normal soda lye* .....	100 ccs.
Sodium sulphite, 6 per cent. sol. ....	100 ccs.
Thio-indoxyl .....	15 gms.
Water .....	1000 ccs.

### Examination of the Image Developed with Indoxyl and Thio-indoxyl.

Examined by daylight, the image developed with indoxyl appears green, that with thio-indoxyl orange-yellow. Both show a strong metallic lustre by reflected light. Superficial observation at once shows that the images are not of a homogeneous nature, but consist of indigo or thio-indigo and metallic silver. Both images—the “indigo image” and the “silver image”—can be separated one from the other without difficulty.

\* Strong solution of caustic soda.

If the plate developed with indoxyl, after washing, fixing, and hardening with alum, is transferred to a solution of potassium cyanide, the silver image will dissolve, whilst the indigo image which is now pure blue, remains behind. In the same way there can be obtained from the plate developed with thio-indoxyl the red thio-indigo image. If, on the other hand, plates are immersed in a weak solution—3 to 5 per cent.—sodium hydrosulphite ( $\text{Na}_2\text{S}_2\text{O}_4$ ), the indigo image is reduced and goes into solution as colourless indigo white, leaving the silver image behind. The latter appears brown by transmitted light; by reflected light, white, with metallic lustre similar to the physically developed image on a wet collodion plate. From the used hydrosulphite solution blue flocks of indigo or red flocks of thio-indigo separate out on exposure to the air.

The plates developed with these two substances can be bleached with mercuric chloride in the ordinary way. Naturally, only the silver image is bleached; the indigo or thio-indigo images remain unchanged. If the bleached plate is placed in sulphite or ammonia solution, the silver image is blackened in the usual way.

Solarisation phenomena can be carried out with the indoxyl developers; the results are far more certain than when an ordinary developer is used. Excellent duplicate negatives can be prepared by this method.

Both for transparencies and bromide paper beautiful results can be obtained by means of these developers; the method is obvious from what has been said above.

DR. B. HOMOLKA.

## THE EXHAUSTION OF THE FIXING BATH.

WHEN a number of plates are successively fixed in a solution of hypo, a time comes when, before complete exhaustion of the solvent power of the bath, it is advisable to reject the solution, because the plates fixed under these conditions may subsequently, if insufficiently washed, show various changes, and particularly a brown stain.

The question is to know within what limits the bath should be used in order to avoid these changes. Gaedicke attempted to elucidate this point by an interesting study,<sup>1</sup> starting from the principle that there was identity between the discoloration of badly washed plates which had been fixed in a partially exhausted bath, and the browning very rapidly obtained on exposing, to air and light, paper impregnated with hypo solution with a sufficient addition of silver nitrate. By determining experimentally the minimum quantity of silver nitrate which must be added to a given solution of hypo to cause the commencement of yellowing and converting these results into silver bromide, Gaedicke deduced the limit of the use of a fixing bath.

Assuming that one admits that the same double salts are formed when sodium hyposulphite acts with silver nitrate as with silver bromide, the conclusions drawn by Gaedicke seem rational, but the principles on which the experiments were based not appearing to us to be quite precise, we proceeded to verify them.

For this reason we have repeated Gaedicke's experiments, and substitute bromide for nitrate of silver—that is to say, we have worked under conditions practically identical with those that occur in practice, and have also investigated the influence of the concentration of the fixing bath, and that of the various additions, such as sodium bisulphite and alum.

In all our experiments we have added increasing weights of silver bromide, well washed and pure and prepared in the dark to the same volume of solution of hypo.

A first series of experiments were made with solutions of hypo

from 5 to 45 per cent., so as to determine the influence of the strength of the hypo solutions on the use of the bath.

In a second series of experiments we added to a normal solution of hypo, 15 per cent., the usual quantities of sodium bisulphite and chrome alum, and we have tested whether these additions exert any action on the phenomena.

For each test a drop of the solution was placed on filtering paper and then exposed to the air and light.

We have determined in every case the maximum weight of silver bromide which can be dissolved in each solution of hypo without producing the brown discoloration.

The results of our tests are given in the following tables:—

A.—The Effect of the Strength of the Hypo Solution.

Strength of the hypo solution.	Weight of silver bromide which can be dissolved in 100 ccs. of the solution.	Maximum weight of silver bromide which can be dissolved without causing subsequent yellowing of the negative.	Ratio between the maximum weight of silver bromide dissolved and that which will cause subsequent yellowing.	Weight of silver bromide calculated as necessary to form the compound $\text{Na}_2\text{S}_2\text{O}_3 + \text{Ag}_2\text{S}_2\text{O}_7$ .	Ratio between the maximum weight of silver bromide dissolved and the weight which corresponds to the compound.
5 per cent.	2 gms.	1.25 gms.	62 p.c.	3.8 gms.	33 per cent.
15 „	6.3 „	3.8 „	60 „	11.4 „	33 „
45 „	20.5 „	5.6 „	24 „	34.2 „	15 „

B.—Action of Sodium Bisulphite with and without Chrome Alum

15 per cent. hypo + 1.5 per cent. acid bisulphite	6.3 gms.	3.8 gms.	60 p.c.	11.4 gms.	33 per cent.
15 per cent. hypo + 1.5 per cent. bisulphite	6.1 „	1.65 „	27 „	11.4 „	14.5 „
15 per cent. hypo + 0.5 per cent. chrome alum	5.9 „	2.2 „	38 „	11.4 „	20 „

<sup>1</sup> “Eder's Jahrbuch,” 1906, p. 64.

These results, compared with Gaedicke's, proved that it is possible to add considerably more silver bromide than silver nitrate to a solution of hypo. Gaedicke found, in fact, that in order to entirely avoid subsequent yellowing, a 15 per cent. solution of hypo would not stand more than one-tenth of the total weight of silver nitrate without obtaining a precipitate. According to Table A, it will be seen that to a 15 per cent. solution of hypo no less than 60 per cent. of silver bromide corresponds to saturation.

It will be seen, moreover, that all conditions being equal, dilute solutions permit one to use the hypo solution more, and at for the same concentration the solutions acidified with sulphite cannot be exhausted so completely as those not acidified. The proportion of hypo that can be used is reduced in this case from 60 to 27 per cent., but the latter figure is raised to 38 per cent. by the addition of chrome alum.

If one calculates from these results the number of 9 x 12 cm. plates that it is possible to fix, without having to fear subsequent yellowing, with a litre of 15 per cent. solution of hypo without the addition of bisulphite and chrome alum, we shall obtain the following results, assuming that each 9 x 12 cm. plate gives to the fixing bath about 0.3 gms. of silver bromide:—For 1 litre of 15 per cent. solution of hypo 100 plates 9 x 12 cm.<sup>2</sup>

For the litre of 15 per cent. hypo plus 1.5 per cent. of sodium sulphite lye about 50 plates 9 by 12 cm.

For 1 litre of 15 per cent. hypo plus 1.5 per cent. bisulphite plus 5 per cent. chrome alum about 75 plates 9 by 12 cm.

In comparing the weights of silver bromide necessary to saturate the solutions of hypo with those which correspond to the formulæ of the double salts which are supposed to be formed on fixing, it will be found that the quantities of the first are considerably lower than the second.<sup>3</sup>

One hundred 9 by 12 c.m. plates corresponds practically to 1678 sq. inches.—"B.J."

It is admitted that the following three compounds may be formed in fixing a plate when using increasingly small quantities of hypo in proportion to the silver salt: 1. Double hyposulphite of soda and silver  $\text{Ag}_2\text{Na}_4(\text{S}_2\text{O}_3)_3$  with three molecules of hyposulphite of soda to two molecules of silver bromide. 2. Double hyposulphite of sodium and silver  $\text{Ag}_2\text{Na}_2(\text{S}_2\text{O}_3)_2$  with two molecules of hypo to two

Thus 100 cc.s of 15 per cent. solution of hypo, that is, 15 gms. of the crystallised salt, dissolve 6.3 gms. of silver bromide. This saturated solution, being made in the presence of an excess of silver salt, ought to form  $\text{Ag}_2\text{Na}_2\text{S}_4\text{O}_6$ . But this salt theoretically requires 11.4 gms. of silver bromide for 15 gms. of hypo, or almost double the quantity corresponding to saturation. This saturation takes place, moreover, without the formation of a white precipitate insoluble in water, easily decomposable into silver sulphide, which characterises the precipitated salt  $\text{Ag}_2\text{Na}_2\text{S}_4\text{O}_6$ , which is obtained on adding silver nitrate to sodium hyposulphite.

The relative weights of silver bromide and sodium hyposulphite in the solutions saturated with silver bromide to any of the formulæ for the substances which have been so far considered to be formed in the solution.

The reactions which are produced in the fixation of bromide of silver plates do not appear to take place as is generally indicated. This question we propose to study in a subsequent research.

### Practical Conclusions.

To avoid subsequent yellowing of negatives on gelatino-bromide plates, it is advisable:—

1. Not to fix more than one hundred 9 x 12 cm. plates in 1 litre of 15 per cent. solution of hypo.

2. Not to fix more than fifty plates in a 15 per cent. fixing bath plus 1.5 per cent. of bisulphite.

3. Not to fix more than seventy-five plates in a 15 per cent. fixing bath plus 1.5 per cent. bisulphite plus 0.5 per cent. chrome alum.

4. One can practically recognise the moment when the fixing bath should be thrown away by placing a drop of the bath on paper and seeing whether the spot turns brown when it is exposed for some time to light and air.

A. AND L. LUMIERE AND SEYEWETZ.

molecules of bromide. 3 Silver hyposulphite  $\text{Ag}_2\text{S}_2\text{O}_3$  with a small quantity of hypo for an excess of silver salt. The first salt is white, insoluble in water, soluble in hypo. The second is white insoluble in water and hypo. It slowly decomposes in light giving sulphide of silver. Finally the third salt is decomposed almost as soon as formed, and gives silver sulphide.

## DIRECT CARBON ENLARGEMENTS AND OZOBROME.

In our issue for April 20, 1906, page 305, we published an article by Dr. Hiecke, of Vienna, describing his method of making direct enlargements on gum-bichromate paper. In the current number of the "Photographische Mitteilungen" Herr Hans Schmidt describes the use of a new paper by means of which enlargements can be made direct on to carbon tissue.

The author points out that the majority of work at the present time is, certainly for outdoor exposures, done on small plates; and whilst these small sizes are very convenient, the prints are too small for decorative purposes, therefore enlarging comes more and more to the front.

The two methods most usually adopted to obtain large prints are direct enlarging on to bromide paper, and indirect enlarging, in which a positive is first made by contact, and then this is enlarged on to a dry plate or negative paper, and the large prints obtained then by contact printing.

Enlargements in carbon have nearly always been made by the indirect method, and if all the delicacy of the carbon process is required it is essential to use glass negatives. If there was a simple method of enlarging direct on to carbon tissue the enlarged negative would be done away with, and thus considerable trouble and cost be saved.

This has now become possible by the two following processes:

### Carbon Enlargements with Silver Bromide Pigment Paper.

As in the ordinary process of bromide enlarging the paper used for this process must be manipulated in the dark room. Any daylight or artificial-light enlarging apparatus can be used, and the focussing, etc., is as usual.

The light-sensitive film is, as the name implies, nothing more than an intimate mixture of the two films of silver bromide and carbon papers.\* The silver bromide pigment paper has the dark appearance of ordinary carbon tissue, and the light-sensitiveness of a bromide, and this explains the necessity of manipulating the same in the dark room.

The method of working is as follows:—The exposed paper is immersed in an iron developer, without preliminary soaking in water, and with correct exposure development will be complete in about five minutes. With the lighter-coloured tissues the progress of development can be easily seen, especially when a bright red or deep yellow dark-room lamp is used. Develop-

\* Compare Koppmann's silver bromide carbon process in Vogel's "Das Pigmentverfahren," 5th edit., p. 85. In our issue for November 25th, 1904, will be found Riehensahn and Posselt's patent for a similar tissue, and an addition thereto is recorded in our issue for May 12th, 1905, p. 367.—EDS. "B.J."

ment may, however, be done according to time if careful attention is paid to the constant composition and temperature of the developer.

The ferrous oxalate developer should alone be used, because other developers always more or less tan the gelatine, and therefore make the subsequent development with warm water impossible. When development is complete, the paper, without washing, is immersed in water acidulated with acetic acid for about half a minute, and then washed for two or three minutes in running water.

The washed paper is then immersed in the following bath, which can be repeatedly used, for three minutes:—

Potassium bichromate, 4 per cent. solution ..... 100 parts  
Alum, 10 per cent. solution ..... 5 "

It is then washed for about three minutes in running water.

By treating it with the bichromate bath, the following change takes place:—The silver image produced by development acts on the bichromate and the new compounds formed tan the gelatine in proportion to the amount of silver present. If the paper is then placed in warm water the unhardened gelatine dissolves, and with it the imbedded pigment is carried away. In order that there may be no loss of fine details, the silver bromide pigment paper must be developed on a transfer paper as in the ordinary carbon process. Either single or double transfer may be used. If single transfer is used the print will be laterally reversed of course, but this can be put right in the enlarging of the negative.

### THE OZOBROME PROCESS.

As the principles and practice of the Ozobrome process are no doubt article by some extracts from a new edition of the instructions for additional hints thus published will be appreciated by those who have

Ordinary acid alum fixing baths for the bromide or gaslight print are not recommended, but a very useful formula for chrome alum fixing and hardening bath is given below.

There are two methods of bringing the plaster and print into contact, and it is important to bear in mind that any excess of pigments solution beyond that which has been absorbed by the gelatine film of the plaster might injure the delicate tones of the resulting picture. It is, therefore, necessary to remove or disperse any superfluous solution remaining on the surface of the plaster before it is brought into contact with the print. This is accomplished by drawing the soaked plaster once or twice along the surface of clean cold water.

#### Squeegeeing for Small Work.

Lift the soaked plaster from the pigments bath, allowing the excess of solution to drain off. Now draw the plaster, face downwards, across a surface of cold water (the water in which the bromide print is lying will do) and, after draining, bring it at once into contact with the print under the surface of the water, then lift the two papers, clinging together, out of the dish and squeegee them into contact upon some smooth hard surface, such as a sheet of plate glass. Any adjustment of the papers should be done immediately after removal from the water.

#### Possible Difficulties.

*Loss of Detail in High Lights, Patchiness in Skies and Dark Marks.*—If the soaked plaster is taken direct from the pigments bath and brought immediately into contact with the bromide print, the excess of solution on the surface of the pigment plaster will most probably act upon the image before the film of the pigment plaster can be brought into close contact. This gives rise to patchiness, dark marks and loss of delicate detail. Always remove the superfluous pigments solution by drawing the gelatine surface of the pigment plaster over clean water before bringing it into contact with the bromide print.

Another possible cause of general softness of the gelatine film and consequent washing away of high-lights, may be that the working pigments solution has become contaminated with gelatine dissolved out of the plaster. In this case the addition of alum is necessary, thus:—Add 15 to 20 minims of a 5 per cent. solution of ordinary

The prints after development have a somewhat milky appearance, which is caused by the imbedded silver bromide. To remove this the print should be immersed in a 1 : 5 hypo solution for about five minutes. This gives the prints great brilliancy and a rich colour. After this the print can be brought out into full daylight; weak daylight or lamplight can, however, be used after the chromate bath has been applied. Only the first manipulations must be done by dark-room illumination.

When the pigment print is thoroughly fixed it should be washed in cold water, hardened, and dried. It is then ready for mounting and retouching.

The carbon print thus obtained is quite permanent, notwithstanding the metallic silver imbedded in it. If, however, it is considered desirable to remove this silver image, the ordinary hypo and ferricyanide reducer should be used instead of the fixing bath. The print naturally becomes brighter than as the dark silver image is dissolved. This is one way of making a picture which is too dark somewhat brighter. Conversely, by intensifying the silver, a print that is too light may be made darker.

It is obvious that contact prints can also be made by contact printing. The process is precisely the same as outlined above, with the advantage that carbon prints can be quickly prepared by artificial light. For contact printing the negatives should have a safe edge, and in order to avoid laterally reversed prints film negatives should be used and printed with the celluloid next the tissue; exposure can be made to weak day or lamplight.

familiar to our readers, we may appropriately supplement the above the Ozobrome process issued by the Ozotype Company. The additional hints thus published will be appreciated by those who have

alum to each ounce of concentrated pigments solution contained in the working bath. An excess of alum gives flat pictures.

N.B.—It is strongly recommended to add the above quantity of alum to a pigments bath that has been used for about eight whole plate pictures, or their equivalent in surface.

*Pictures are Flat and Difficult to Develop.*—This trouble may arise from hypo remaining in the bromide print. One remedy is to soften the gelatine so that the development may be easier. This can be effected by adding acetic acid to the working pigments bath in the proportion of two to three drops of glacial acetic acid to each ounce of concentrated solution contained in the working bath. A difficulty in development may be caused by keeping the plaster too long in contact with the print or transfer paper.

*Frilling.*—The edges of the plaster frill up during development. This may be caused by using a plaster smaller than the bromide picture. See that the plaster completely covers the picture with a margin to spare. No safe edge is required when the above precaution is taken. All the Ozotype Company's pigment plasters are cut to allow such a margin.

Frilling may also be occasioned by the plaster being saturated with water when transferring, in which case it fails to adhere firmly to the transfer paper. With very rough papers, lack of pressure after transferring, or allowing insufficient time between transferring and developing may give rise to the same trouble.

If the plaster backing is stripped before the gelatine commences to dissolve at the edges, frilling at the corner may be experienced.

*Specks and Airbells.*—In all stages of the process look out for airbells and remove them. Bear in mind that all surfaces should be brought together either under water or with a layer of water between them, and that the water itself should be free from airbells. The critical moment to look for airbells is after stripping the plaster from the bromide print. The transfer paper lying in the same dish is very likely to catch a crop of small airbells, which, of course, must be removed before bringing the papers into contact. It is a good plan to strip the plaster in a separate dish of cold water.

#### A Fixing Bath for Bromide Originals of Ozobrome

Should the plaster, through loss of moisture in dry weather, assume

obstinate curl, pass a sponge (dipped in cold water and squeezed) over the gelatine surface, and after a minute or two it will become flat and pliable. In this case the plaster should remain in the mounting bath a little longer time.

Thick and thin transfer papers require to be soaked 10 to 20 minutes before the application of the pigment plaster.

A hardening and fixing bath combined is very convenient when using bromides for ozobromes, and the following bath has been found to work very satisfactorily.

#### HARDENING AND FIXING BATH.

Water .....	80 ozs.
Hypo .....	12 ozs.
Potass metabisulphite .....	1 oz.
Chrome alum.....	1 oz.

## MODERN METHODS OF PHOTOGRAPHIC MOUNTING.

(A paper read before the Sutton Photographic Club.)

THROUGH the remarks which follow I have mainly in mind the requirements of the ordinary amateur who occasionally wishes to show his prints in public at exhibitions, to hang them on his walls, to send them in to competitions, some of my observations will, I venture to think, be not unhelpful to those professionals who realise that they may at times do better than abandon their prints to the tender mercies of the "stock" mount.

I also confine myself mainly to prints whose size and character do not demand the employment of close framing. I cannot do better to commence with than remind you of Alfred Stevens's well-known dictum: "A picture, like a pretty woman, needs ornament." The next reminder is that all present methods have been derived from previous ones. The most prevalent theory of photographic mounting was at one time what may be termed the "in-the-wall" one. According to this, the beholder was supposed to regard the print as being seen through a rectangular other shaped opening in a wall. This idea was in harmony with the "hold-the-mirror-up-to-Nature" notion of what was formerly considered first-class photography. But to-day the trend of opinion is to treat the mount as part and parcel of a decorative unit, of which the chief feature is the photograph. Before coming to some general principles which are more or less universally accepted by those who know, let me interpolate that when I first began amateur photography there were two maxims almost universally accepted: 1. That the four margins should be equal.

2. That an Indian tint plate-sunk mount should be used. Both these canons are now considered to be anathema—the mark of the ignorant.

If you want to be modern—in touch with all that is most asserted—you must, above all things, avoid the centre of a mount. If you want to indicate that you are not ignorant of the elementary principles of æstheticism, beware of using the India tint and the plate mark for photography. They are both in the nature of fads, and are, therefore, odious to all cultivated people. The plate mark is the product of printing an etched or engraved design upon plate paper. Obviously it is a meretricious pretence to mount a photograph, which is essentially not produced by pressure, as if it were a line, mezzotint, or stipple engraving. For a similar reason, the "India tint," which is associated with an engraving, becomes a fraudulent incongruity if used round a photograph. After a while, the India tint mount gave way to the plain white, the cream colour, or the "neutral" tint mount. These, although originally "safe," were considered bare and bald. Besides which, a fashion set in for "all dark" prints; pictures in which the lights are in inverse ratio to what the ordinary observer would picture as natural. At this period the mount almost completely disappeared—least, from exhibition work—prints being framed close, often in oppressively heavy dead-black mouldings.

#### Healthy Variety.

Against this funeral fancy we are now enjoying an acceptable reaction. Moreover, to a large extent, leading amateurs now display

Lumière's "Fixolene" is also strongly recommended for this purpose.

No further hardening of the bromide print is required after these baths.

On stripping the plaster from the bromide print, in Method II., black patches of unchanged silver sometimes remain in the very deep shadows. As a rule these make very little difference in the resulting picture, but they can be avoided by using a stronger pigmentsing solution.

It is most probable that the development in hot water removes all traces of the pigmentsing solution from the print, but, in order to make quite certain, a 5 per cent. alum bath may be used immediately after development.

a liberty of action which indicates that they do not, as of yore, mount their prints entirely according to the prescription of the moment, but employ taste and knowledge to do their best for each individual picture.

That this is a wise practice no one can gainsay, when it is remembered that the photographic print varies almost without limit as regards the vigour of its rendering and the colour of its image.

We can all obviously realise that a red-brown P.O.P., a black platinotype, and a sea-green carbon each ask for a different treatment as regards mount. Those who are adepts at mounting are able to distinguish just as clearly what are the precise shades of tinted papers which each particular brown, or black, or green, or red demands. For instance, there are possibly as many as twenty distinguishable browns in common use for photo-printing purposes. If it is required to fit these with surrounds which shall be absolutely harmonious, not one nor two, but maybe a dozen different tints of brown paper will be called for. The colour sense is, however, not so highly developed in most people as to make it possible for them to thus ring the changes.

But many will be well able to discriminate between such differences as the "plummy" brown often met with in gold-toned matt silver papers, the vandyke-brown seen in the carbon, and in some measure in the "Japine" paper, and the sepia-like brown which carbon and toned bromide papers at times exhibit. In so far as one can distinguish between one print and another, so may one hope to be sufficiently colour-sensitive as to make a harmonious selection of mount to go with the print. Here let me interpolate two maxims which will at least prevent the tyro from making serious blunders:—

1. The mount should be neither as dark as the print's deepest shadow nor as light as its chief high light.

2. The scale of contrast between one part of a mount and another, or between mount and frame, should be less than that which exists in the print.

EXCEPTION.—In case of some undesirable violence of black and white in a print, an excess of similar contrast between the frame and mount may be serviceable in diminishing the harshness of the print.

#### Harmony or Contrast.

Speaking broadly, there are two courses open in all mounting schemes—viz., to choose a surround which, as regards colour, forms with the print a harmony or a contrast.

A complete contrast is that afforded by the juxtaposition of complementary colours. For instance, a ruddy-brown print surrounded by a cool green would be a case in point. Obviously, the occasions when a direct contrast will be desirable are likely to be few and far between. It is then in the direction of harmony that we must turn for a satisfactory scheme of mounting.

An attribute of good mounting which should always be borne in mind is that the beholder should not be so much struck by the mount that it is found to be more attractive than the print. Indeed, it is a sound maxim that the system employed should be

so unobtrusive that one should not be able to remember what the mounting was like. This I have more than once found to be a reliable test to apply to the question. For instance, I recently wanted to refer to the method adopted by that talented amateur, Mr. Alvin L. Coburn, but although I had several times studied his prints at the Royal Photographic Society and at the Salon for journalistic purposes, I could not for the life of me remember what he had used, beyond that his works were hung *en passe partout*. On subsequently taking special notice of those at the Salon, I found that he used a sober neutral tinted paper having a tonal value about half-way between the high lights and shadows of his prints, with a binding strip, but very slightly darker. There was little or nothing to catch the eye and distract attention from the print, and, by the same mark, there was nothing to fix the pattern, colour, or depth of the mount in one's memory.

### American Mounting

So far most of my remarks have had reference to what may be termed plain or single mounting. During the past few years ornamental or multiple mounting has become very popular. The employment of multiple mounting has, so far as photography is concerned, been ascribed to the Americans. Although they did not exactly invent it, they seem to have had a chief share in bringing it into notice or favour.

Multiple mounting consists in fastening two or more sheets of variously tinted paper of different sizes one on the top of the other, so that they show two or more margins of different tints surrounding the print. These margins may vary from 1-16 in.—in which case they may be termed lines—to any width that the mount will allow. As may be imagined, they permit a great play for fancy and for taste, for which reason the multiple mounting system is favoured by the æsthetically-gifted, and disliked by those who feel that it only opens the way to them for a series of blunders.

If I were not addressing an audience highly endowed with decorative instinct I should advise them to give multiple mounting a wide berth. But as it is, inasmuch as this method not only at times helps the effectiveness of the print, but also indicates the cultured taste of the amateur, it is certainly worth while to give careful attention to this refinement of mounting.

### The Choice of Tints.

As regards the tints and surfaces of the paper employed in mounting, I can only spare time for a few words.

As a general rule, the choice of paper will, or should, be governed by the colour of the high-lights of a print, although in some cases it is necessary to give first consideration to the half-tones and shadows. For instance in mounting a print made upon cream-tinted paper it is well that the mount should contain some proportion of such a tint rather than consist of a cold blue-white or a cold grey tint. On the other hand, a pure black-and-white print—such as an amidol-developed bromide on snow-white paper—will, as a rule, not be well served by being pasted upon a cream-tinted mount.

In the not uncommon case of a brown print upon white paper, it will usually be found that a brown-hued mount which is considerably lighter and cooler in tint than the lighter shadows of the print will be the best expedient. Some amateurs have a great fondness for colour in their mounts; occasionally a tolerably bright-tinted mount if there be not too much of it may be advantageous, but its employment needs the taste of one whose colour sense is almost infallible.

In this regard it is well to bear in mind that the larger the surface of the mount, the less pronounced should be its colour and its deviation from half-tone. Hence it is that it is permissible to use a fine white or black, or even bright red, green, blue, or other coloured line surrounding and enclosing a print. Personally

I do not care for the passing fancy of putting a line between the mount and the print, although there are at times sufficient reasons to warrant it.

### Objectionable Shams.

I have already given my opinion about the impropriety of using a sham India-tint mount. Of late, a fashion has sprung up of printing upon sensitised thin cream India paper, or on what is much the same, viz., Japanese tissue, in such a way that there is left a clear margin, so that when the photograph is mounted on any suitable paper, it, as regards "tint," presents much the appearance of an engraving. To thus treat one's print cannot well be cavilled at. The "tint" is not a sham one, and, moreover, the print itself is impressed upon the tint; but when the amateur goes a step further, by so displaying such a print as to make it superficially imitate an old mezzotint, or etching, it should have the strong disapproval of all who dislike deception. Let me explain what I mean. At an exhibition now open are several such prints, which have one edge badly jagged. This imitates the condition of a print which (1) has been torn from a book, or (2) has been mounted without trimming, as it came from the engraver's press. That is, I consider, bad enough. But it is worse still when this affectation is carried to the extent of mutilating part of the actual print, so that the impression may be conveyed that the modern photograph is an old, rare, and precious fragment of some fine etching. This is not art, but chicanery.

### Mounting Materials and Apparatus.

Closely allied with the question of mounting is that of the employment of the *passee-partout* in place of the German—other—moulding. Personally, I much like the *passee-partout*. It emancipates one from the frame-maker, saves the pocket, and permits of the exercise of considerable personal taste. Without dwelling upon the principles which should control this convenient way of binding up print and mount, I should like to briefly refer to some few of the modern facilities for carrying out the practical work of mounting which are at our disposal.

As to mountant. First in my affection stands Higgins' "photo mounter," which has never played me false. For a home-made article nothing beats a light starch jelly, but it only keeps a short while, and many people cannot make it properly. One of the greatest of boons recently introduced is without the shadow of doubt the dry adhesive mounting system. Many of my photographic acquaintances who have adopted it speak most enthusiastically of it, and at least one important firm—viz., the Platinotype Co.—specially recommend it to all their customers. Some people think that it must be difficult to manage. All I can say is that I procured one of the hot presses (which are now obtainable for a few shillings), and with only a printed slip of directions to guide me straightaway dry-mounted a P.O.P. An important matter in mounting is that of trimming a print. To carry out this, knives, cutters, cutting shapes, set squares, cutting boards, and similar contrivances which out end are provided. I show a selection of such articles, which explain themselves. But what I now use, to the complete exclusion of all the above more or less troublesome odds and ends is Merrett's trimming desk. I find it cuts prints more accurately, in about one-tenth the time needed when using the knife, etc. As regards paper on which to mount, I can say that those of you who are in dead earnest should do as many others do before you have, viz., get from twenty to thirty or more sheets of paper of such various delicate tints and tones as are likely to best accord with your prints; then, when you are mounting a picture for exhibition or for the wall of your room, try to harmonise what texture and what tint or tints will be most harmonious and effective. I can suggest no simpler course than this.

HECTOR MACLEAN, F.R.P.S.

THE TWENTY SECOND ANNUAL EXHIBITION of the Birmingham Photographic Society will be held from the 23rd inst. to March 4 at the Royal Society of Artists. The exhibition promises to be of great interest. In addition to many well-known English workers, the list of exhibitors again includes many entries from abroad, fifty-seven names figuring in this section, and the work reaching a very high average of merit. The educational value of such a collection is beyond question. Apart from the pictorial section, technical photo-

graphy is well represented by (among others) a series of photographs illustrating the application of the camera to the detection of crime (by Dr. Reiss, of Lausanne), another set taken from a balloon at varying altitudes, and a third (sent from Bombay) illustrating Indian characters and buildings.

ERRATUM.—The Jandus Arc Lamp and Electric Company ask us to correct an error in their letter of last week. The visual power of the Jandus flame arc should be 20 instead of 50.

## NON-AQUEOUS MOUNTANTS FOR PRINTS.

(From "Deutsche Photographen Zeitung.")

The ordinary paste of wheat or rice starch can be made but slightly soluble in water, and not completely insoluble by astringents.

The cheapness of starch paste and its great adhesiveness are the chief reasons for its general use, not only in photography, but also for many other purposes. Its only disadvantage for mounting prints on cards is the curling or distortion of the cards in consequence of the middle being damped, whilst the edges and back remain dry.

The quicker and more evenly the starch dries the more even and flat will be the cards when dry; the damper they are the more they will be distended. The best way is to mix the two kinds of starch thus:

Purest wheat starch .....	40 parts
Purest rice starch .....	20 parts.

They should be finely powdered and thoroughly mixed in a mortar. The following solution should then be made:

Gelatine .....	5 gms.
Water .....	250 c.cs.

Allow the gelatine to soak in water and then dissolve by boiling. The solution should be fairly thin and quite clear; then it should be cooled down to 68 deg. F., and the mixture of the starches added in small quantities, with constant stirring, till a milky mixture is formed.\* It should be now slowly heated to boiling point, and with constant stirring evaporation continued till about one-fifth of the

\*The writer omits to say what weight of the starch mixture is to be added, but may be supposed that he intends "parts" written in the first formula to be read grammes.—Eds. "B. J."]

liquid has evaporated. Finally, to the mixture which becomes thicker and thicker should be added—

Alcohol (60 deg.).....	20 c.cs.
Oil of cloves .....	2 c.cs.

and the mixture allowed to cool. This keeps in well-closed tubes or vessels perfectly for a long time without going bad or acting prejudicially on the prints. The adhesive power of this mountant is very high, and with careful preparation is perfectly uniform throughout.

All these pastes can be made less soluble in water by adding, as already pointed out, astringents such as alum, formaline, etc., in small quantities. After such additions, the paste, when once dry, dissolves much less readily; but this can hardly be considered as an advantage in the face of the disadvantage that such additions may act on the prints.

As regards insolubility in water, resinous compounds should alone be considered, which should either be dissolved in suitable solvents or rendered liquid by heat, so that the resin forms a connecting film between the print and card.\*

C. HARTMANN.

[\*The writer proceeds to give directions for the preparation of an adhesive tissue, apparently in ignorance of the fact that the process is that covered by the Derepas patent and owned in this country by the Adhesive Dry Mounting Company, Limited. It should be understood that the use of a shellac or other tissue (for mounting purposes) employed with heat constitutes the patent in question.—Eds. "B. J."]

## FOREIGN NEWS AND NOTES.

### Daylight Development.

DR. B. SZILARD and M. PASZTOR, of Budapest, have taken out a German patent for the use of a solution composed of 2 parts chloroxy-phenylchinoxalin, 3 parts of phenolphthalein in 50 parts of alcohol and 50 parts of glycerine. A few drops of this, added to an alkaline developer, produces at once a deep red colour. In the case of an acid developer a few drops of caustic soda should be added to the above. The developer must be at least four-fifths of an inch deep above the surface of the plate. The progress of development can be watched without the use of a dark-room or removing the plate from the dish. Any coloration of the film is removed by subsequent washing, and, if necessary, the use of an acid bath. We presume that the use of these two particular compounds is alone patented, as in 1889 and 1892 the use of a mixture of colouring matters was patented in England, and more recently still we have had the preparation sold as "Coxin."

### A Reducer for Gum Bichromate Prints

MR. G. SCHWEITZER states in "La Revue de Photographie" that he has found eau de javelle—about 2.3 per cent.—an efficient reducer for over-exposed gum-bichromate prints. It can be also locally applied with excellent results. Apparently it attacks the underlying parts and not the surface of the image if allowed to act too long. The use of this solution as well as that of chloride of lime and of chlorine water was suggested by Wharton Simpson in 1868 for reducing carbon prints. To some enthusiastic gum workers, the use of any chemical as a reducer will probably savour of heresy as being too scientific, and will not replace mechanical attrition.

### Catatype.

At a meeting of the Deutsche Gesellschaft für Freunden der Photographie last month, Herr Hans Schmidt gave a demonstration of this process, which is based on the discoveries of Professor Ostwald and O. Gros. ("B. J.," 1903, pp. 43, 144, 464.) The materials for the process have been introduced commercially, after four years of research, by the Neue Photographische Gesellschaft, of Berlin. The negatives have to be made on special bromide paper, and developed and fixed in special baths. They are then rubbed over with "Perisol," a special solution of hydrogen peroxide, and placed in contact with a special positive paper, and left for two minutes under pressure.

In the positive paper when stripped, there is a positive consisting of hydrogen peroxide, which, when immersed in a solution of a manganese salt, reduces the latter and forms a brownish yellow material image. Dozens of prints can be obtained from the one negative, and by the use of various solutions they can be toned to different colours, such as olive, light and dark green, reddish and bluish violet, brown, black, etc. These are stated to be permanent and capable of considerable variation to suit the class of negative. Variations in gradation of the prints is possible by suitable treatment of the negatives.

By squeezeing the peroxide negative to carbon tissue containing a cobalt salt, the latter is acted upon by the peroxide and tans the gelatine, the subsequent treatment of the carbon prints being as usual.

THE ANNUAL EXHIBITION of the Club des Amateurs Photographes de Belgique will be held at the club's premises, La Maison du Livre, Rue Villa Hermosa, near the Place Rozale, Brussels, from the 1st to 18th March.

TRADING BY STAMPED POSTCARDS.—In "Trading Made Easy," a pamphlet which is also a petition to the Postmaster-General, Mr. Charles A. Houfe suggests that the public should be allowed to affix the address side of a postcard stamps to the desired value (as the

custom grew, stamps of larger denominations would be used) in payment of an order written on the letter side—the stamps being cancelled by the sender writing his name across them, but the recipient receiving credit for the amount. The author contends that trading between persons 300 miles apart would thus be as simple as in a shop, and he meets various objections that might be raised to his scheme. The Government could (if it chose) take its usual commission from the recipient of the spoiled stamps.

## LANTERN ILLUMINANTS.

The estimation of the intensity of a light is generally made by the ordinary person by the mere visual brightness, but as pointed out by Herr W. Süss in "Die Photographische Industrie," this is by no means a guide as to the value of the light in the lantern. An important point in a lantern illuminant is its area, and not only as regards height and breadth, but also depth. Only those rays emitted by a source of light in the focus of the condenser are really utilised in the projection of a lantern slide, and those rays, which are considerably beyond or outside the focal point of the condenser, are practically lost. The less the area of a light the more its rays are utilised in projection.

The construction of the condenser has also to be taken into account. The most general form consists of two plano-convex lenses with their convex surfaces together; frequently, too, a triple condenser is used, in which the lens nearest the light is a meniscus. This form has a somewhat shorter focus than the ordinary plano-convex form, and therefore actually gathers up more of the light. If the source of light is considered as the apex of the angle of rays emitted, the closer this is placed to the condenser the more rays will be utilised. The advantage of the triple condenser is particularly seen the closer the source of light approaches the form of a point.

The difference in the intensity of the most usual forms of lantern illuminants with the ordinary and the triple condenser, is well shown by the accompanying table. They were first tested burning free, that is not in the lantern, and then in the lantern, the objective of which was invariably placed at the same distance from the photometer as the naked light was. The lens used was in all cases the

same, and a Hefner amyl-acetate lamp was used as a standard. The results obtained with the lantern are naturally only relative as com-

Light.	Naked light.	In lantern with double condenser.	Percentage of light utilised.	In lantern with triple condenser.	Percentage of light utilised.

Strong arc lamp (alternating) .....					

pared to those of the naked light, as in the use of lenses of shorter or longer focus, the divergence of the light rays will be less or greater. Another factor which must be taken into consideration is also the greater or less pressure of gas or the strength of the electric current. The unit adopted here is the Hefner amyl-acetate candle. The standard candle = 1.14 Hefner.

The results show conclusively the advantages of the triple condenser.

\* Dry plates were not distinguished in the returns used in this country prior to 1903.

THE FUNERAL took place at Normacot churchyard, Longton, last week, of Mr. Arthur Bott, photographer, of Market Street, whose death occurred at the early age of forty-five.

MR. R. H. BOW.—The Royal Photographic Society has sent Mr. R. H. Bow its congratulations upon his eightieth birthday, and has expressed its appreciation of his early researches in the field of photographic optics, and especially of his investigations into the aberrations of photographic lenses.

SEQUEL TO THE FAKED PHOTOGRAPHS CASE.—It was inevitable that the recent lawsuit brought by Miss Gertie Millar should be re-echoed on the stage of the Gaiety Theatre. The echo takes the form of a song in "The New Aladdin," entitled "My Photographic Girl" and sung by Miss Millar.

## Photo-Mechanical Notes.

### The American Photo-Engraver.

LECTURING at the L.C.C. School of Photo-engraving, Bolt Court, on Thursday, February 14, Mr. William Gamble gave some impressions of the American photo-engraver gathered during a visit to the United States. He confined himself chiefly to the business methods of the process firms in the United States, and mentioned, as the chief cause of their economical working, the astute management of the staff, under which every man was kept fully employed. "Hustle" in America did not mean hurry or bustle: it meant uninterrupted work. The actual time taken on a job was not less than in England, but in an American shop there were no loiterers to be found, and if the work did not keep the whole staff employed those not wanted were promptly "fired." The workmen in the States accepted this state of things as a natural condition of business life. The machinery of an American process shop had to move in time with the "hurry up" clerks of the firms ordering the work. Blocks were hurried up with the same energy by these clerks specially appointed for the purpose, whether wanted immediately or months later. As a result, the photo-engraver has a boy in each shop whose sole duty it was to know the progress of each individual job, and to have the information ready at once, in response to the telephone from his chief's office. The business and travelling side of the business are equally well looked after, and the principals, as in other American houses, are on the spot at 7.30 in the morning, and have their travellers on their rounds before nine o'clock. One traveller informed Mr. Gamble that he called on several firms, who would not see him after 9 a.m.

### Book Plates as a Photo-Engraver's Specialty.

"The American Printer," in its February issue, quotes the experience of a firm of photo-engravers, the Eclipse Electrotone and Engraving Company, of Cleveland, in supplying designs and blocks for book plates. The result, it appears, of constantly pushing this small side-line of the photo-engraver's business has been to get orders for the larger and regular supply of half-tone and colour blocks. The Eclipse Company write:—

"As a matter of very cold fact, we derive less revenue from book plates than from any other single feature of our business. Too much time is always spent over the designing and preliminaries that is not charged for—crankiness, hobby, or sentiment, we don't know

which, but can't reform. Nevertheless, as an attractive feature to exploit, I believe it pays to thus 'play up' to the existing fads and requirements of the plate-buying public. It all helps to 'get 'em coming' for all classes of work.

"Some collectors have two ex libris plates—one for the library major and one for the library minor—pamphlets, scrap books, etc. not bad.

A Book Plate of the Eclipse Electrotype and Engraving Company.

"Another thought; labels are book insurance—not so liable to be stolen or go astray; sort of freemasonry signed by a label.

"Some go still farther and have a plate for every subdivision, as one for historical books, one for belles lettres, one for fiction, one for verse, one for science and philosophy, and so on—but that seems to be riding a hobby too hard.

"What we said about prices at the outset must be taken generally. Sometimes we can make a lower price, and often do, even after quoting a higher; sometimes we must ask more in the first place, but in this case, if it costs us more to turn out, we never bill you higher than quotation.

"If one likes copper-plate effects, but does not care to go to the expense of copper engraving and printing, we can approximate with unusual fidelity by using a special paper and a special ink, of which we know. The only handicap is that such labels cannot well bear library numbers, as some writing inks spread badly on this paper. The cost, however, is very little greater than ordinary half-tone work.

"Dry point etchings on copper are a luxury, specially appropriate for libraries of fine bindings, of collections on art, and artistic objects."

#### PHOTO-MECHANICAL PATENTS.

The following patent has been applied for:—

**GREEN GEAR.**—No. 3,194. Improved construction of appliances for indicating and placing in the proper position Levy or similar screens with regard to the sensitised plates or films for photographic purposes. Ernest Howard Farmer, 173, Fleet Street, London.

**LA REVUE DES SCIENCES PHOTOGRAPHIQUES**, the French journal dealing with the scientific aspects of photography, has been amalgamated with "La Photographie." The combined magazine is published by M. Charles Mendel and Co., under the editorship of Dr. Dwenglowski.

**THE PHOTOGRAPHIC STUDIO** in Reid Street, Millport, Scotland, owned by W. Fergus, was totally destroyed by fire last week. The studio and contents were entirely consumed.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between February 4 and 9:—

**CINEMATOGRAPHS.**—No. 2,778. Improvements in mechanism employed in the production of cinematograph and microscope pictures and dark slide for carrying sensitive photographic plates for taking impressions. Henry William Hamblin Palmer, 43, St. Martin's Lane, Charing Cross, London.

**PHOTOGRAPHY.**—No. 2,862. Improvements connected with photography. John Smith Raworth, Queen Anne's Chambers, Westminster, London.

**LENS HOODS.**—No. 2,912. Improvements in making hoods for cameras. Julius Daniel Garfield and Charles Bauer Harris, 40, Chancery Lane, London.

**CINEMATOGRAPHS.**—No. 3,119. Moving picture machine. Enoch J. Rector, 18, Southampton Buildings, London.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**DISHES.**—No. 1,883. 1906. The invention consists of a dish or tray, the sides being made to slope inwards, making an angle of about 15 degrees with the vertical, instead of being upright, or being made to slope outwards. A dish or tray measuring 15 x 12 inches at top would measure about 16½ x 13½ inches at the

bottom, and the sides of all other sizes slope inwards in a similar manner, the benefit being an absence of splash or waste. Each dish or tray will have a lip at one corner, and all sizes over 9 x 7 inches, made in metal, will have a swing handle at each end. Samuel Dawe, 12, St. Andrew's Road, Southsea; and James Cook Thompson, 23, Elm Grove, Southsea.

**CINEMATOGRAPHS.**—No. 18,962. 1906.—The invention, which is an improvement on the apparatus described in Letters Patent No. 25,625, of 1897, has for its object a means of transmitting a positive movement of the driving pins into and out of the perforations in the photographic film, and includes a cam to give a vertical reciprocating movement, and an eccentric to give a horizontal movement, to the said driving pins. William Cecil Jeapes, 154, Charing Cross Road, London, W.C.; and Percy Henry Bastie, Greenland Place, Camden Town, London, N.W.

The following complete specifications are open to public inspection before acceptance under the Patents Act, 1901:—

**BROMIDE PRINTING.**—No. 2,349. Apparatus for the automatic rapid and uniform printing, controllable at will, of positive photographs by gelatine-bromide cottillon.

**COLOUR PHOTOGRAPHY.**—No. 2,461. Bleach-out process. Smith and Merckens.

**SENSITIVE COLOURS.**—No. 2,462. Sensitising bleach-out colours. Smith and Merckens.

#### New Trade Names.

**DIAMALTY.**—No. 284,957. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives.

Henry Algernon Taylor and Douglas Day Taylor, trading as The British Diamant Company, 13, Southwark Street, London, and Sawbridgeworth, Hertfordshire, manufacturers. July 27, 1906.

GRIPON (design of two linked figures).—No. 288,855. Chemical substances used in manufactures, photography, or philosophical research. Pinchin, Johnson, and Co., Ltd., 23, Billiter Street, London, E.C., varnish colour manufacturers. December 15, 1906.

CYCLOPS.—No. 289,179. Lantern slides, photographic. Frank Percy Smith, 15, Cloudesley Place, Islington, London, N., civil servant. December 31, 1906.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### The Removal of Abrasion Marks from Gaslight and Bromide Prints.

In an article in "Photography," of February 19, on "Economy in Bromide and Gaslight Printing," the Rev. A. E. Bloxsome Day recommends the use of the Wellington and Ward iodine formula for the removal of abrasion marks and reduction of density. The prints are fully exposed, fully (i.e., over-) developed, and after fixing and thorough washing, immersed in:—

Potass iodide .....	30 grs.
Water .....	10 ozs.
Iodine .....	3 grs.

until the high-lights turn blue. They are then transferred to a clean fixing bath for five minutes. The reduction in this bath is very great, but if diluted with three times its bulk of water and used for only one minute the bath has no reducing action, and abrasion marks are removed.

### Thickened Developer.

The use of a developing-solution of increased "thickness" (viscosity) is recommended in "The Amateur Photographer" of February 19 by Mr. T. T. Parker, on account of the greater softness and freedom from halation of the negatives. A developer employed with success was:—

Metal .....	$\frac{3}{4}$ gr.
Hydroquinone .....	3 grs.
Sodium carbonate (cryst.) .....	27 grs.
Sodium sulphite (cryst.) .....	12 grs.

These were dissolved in one ounce of water containing 50 per cent., by measure, of treacle.

Other developers, such as rodinal and amidol, have given equally good results, when made up with the thickened solution instead of water. The thickener used has in every case been treacle, of the variety known as golden syrup. . . . The only disadvantages that the writer has found have been, that the time of development is increased, usually by about fifty per cent., and that the dish must be kept rocking; but against these may be put the advantages that the negatives obtained are fine grained, and admirably adapted for enlargement, and that the image, being on the surface of the plate, development is easily followed by the light reflected from it.

### A Backing Hint.

A correspondent sends to "Focus," of February 20, the following account of a simple method he adopts for backing plates. The plates are removed from the wrappers just as they are packed by the makers—viz., film to film. A pair of the plates are then held in the left hand, and the backing is applied to the glass side of one with a camel-hair brush; a mop-shaped brush should be used. Brushing is commenced in the centre of the plate, and the backing worked outwards towards the edges. When one plate is backed in this way, the pair of plates is simply turned over and the other one similarly treated. The plates are then supported until dry. By this means scratches are avoided, and there is no liability of dust settling on the film side.

## New Books.

A UNITED States edition of their 1907 "Exposure Record and Diary" has been published by Messrs. Burroughs, Wellcome and Co., and in most respects similar to the well-known British issue. The monthly tables of light values, however, are calculated for latitude 40 deg. N., and are approximately correct for New York, Chicago, Denver, San Francisco, Washington, Philadelphia, and St. Louis. Light values for use in other latitudes may be calculated by the aid of a table.

## New Apparatus, &c.

The Holos Convertible Wide-Angle Lens. Made by W. Watson and Sons, 313, High Holborn, London, W.C.

Messrs. Watson, whose large aperture convertible "Holostigmat" we were able to report favourably upon a few weeks ago, have now brought out a new lens under the above title, which even in these days of anastigmats of all kinds, may be said to offer the photographer something fresh in the way of optical facilities. That something is the provision in one instrument of (1) a lens of landscape rapidity for average angle work, (2) a lens of extreme wide angle of medium aperture, and (3) two single lenses of about  $f/16$  aperture, double the focus of the complete lens, and covering a plate as long as this double focus. It will thus be seen that the new lens sacrifices something of extreme rapidity in order to provide very exceptional facilities in the way of covering a large plate, and on this account should immediately find favour with architectural photographers to whom great rapidity is of little moment, to whom also a very wide angle lens is frequently a necessity, and to whom, again, and particularly for exterior work, a long focus lens will do what no other could. For these reasons our tests of the No. 8 ( $5\frac{1}{2}$  in. focus) of the new lens were made with some interest and curiosity. The makers list it to cover a whole-plate, and this at the aperture of  $f/22$  we found it to do with excellent definition. As the makers wisely point out, an extreme angle of this kind is to be avoided at all possible, but it is nevertheless satisfactory for the photographer to have the reserve power should it be needed.

The extreme angle that the lens will admit is about 110 deg., which means that with very small apertures it will illuminate as big a plate as is likely to be required. The aperture can be opened out beyond  $f/11$ , but aberration then appears. Tested under trying conditions on a very near object, there was a remarkable absence of distortion on a 12 x 10 plate. With one combination alone, the full marked aperture is  $f/16$ , and with this very good definition was obtained on a 12 x 10 plate. The price, £5 5s., is certainly not out of the way for a lens of such a generally useful type and of such good quality. Very few wide-angled lenses are convertible, and many are of restricted usefulness. The complete lens is an anastigmat. The single lenses show a little astigmatism, but, nevertheless, form very useful landscape objectives.

## New Materials.

"Watalu" Self-developing Plates. Made by Wellington and Warr Elstree, Herts (under license from the Self-developing Plate Company, Ltd.).

These new claimants for the favour, chiefly, we may assume, the amateur photographer, are the outcome of the patents of Messrs. Kelly and Bentham, already recorded in our "Patent News" last year. Unlike the "Amanto" self-developing plate of the Ilford Company, and the "S.D." paper of Marion and Co., the "Watalu" plate has the developing preparation applied to the back after the manner of the Baekelandt water-developing plate which came for a short time upon the British market some fifteen

years ago. But the patentees of the new plate, we imagine, do not put forward any claim to novelty in regard to the backing with a developing composition; their advance consists in the special properties of the composition, which allow it to be preserved intact for a considerable period. As the patents in question were published as early as January of last year it may be assumed that the promoters of the new plates have satisfied themselves of the behaviour of the plates in this respect.

As regards their qualities in practical work, we have taken the occasion to expose a number, and, following the very few directions which are necessary, have found the developer ample for the production of excellent negatives. Although applied to the side of the plate, which is less exposed to the water contained in the developing dish, the white crystalline deposit of developer is very rapidly removed, and is evidently of a highly soluble character. The instructions direct one ounce of water for a quarter-plate, two ounces for a half-plate, and so on, and in the developer which is thus formed the image appears in about a minute, and gradually increases in intensity. The solution shows no signs of staining, in our experience; it was only slightly yellowish after developing six quarter-plates in one dish with six ounces of water.

We wish the new departure every success: it is evidently the result of carefully adjusted manufacturing conditions, and it has besides the great recommendation—namely, that the emulsions in conjunction with which it is sold are those of the well known "Speedy" and "Ortho" plates of Messrs. Wellington and Ward.

**ARTIFICIAL NEGATIVES.**—In reference to the recent article dealing with the making of line negatives by drawing clear lines on an opaque ground of varnish, Mr. James Waddington, of 420, Bolton Villas, Bradford, sends us some specimens of varnish-coated plates applied by him. We find them to be coated with a soft and perfectly opaque varnish which cuts away cleanly under a needle or sharp knife, and permits of drawings or writing being done on the plate with ease. For announcement lantern-slides the plates should be useful to many a lanternist and society secretary. The varnish coating may be protected by applying a shellac varnish.

**MESSRS. A. E. STALEY AND CO.,** 19, Thavies Inn, London, E.C., advise us that supplies of "Defender" papers, bromide, gaslight, and P.O.P., have now reached them, and they are prepared to fill orders promptly. An attractive booklet, dealing very fully with the manipulation of the papers, is ready, and is worth getting, on account of the concise information it conveys on treatment and results. Messrs. Staley, whose announcement appears on page xiii. of this issue, also offer to send a specimen packet of the papers on receipt of two penny stamps.

### CATALOGUES AND TRADE NOTICES

**MESSRS. ROMANET AND GUILBERT,** 26, Red Lion Square, London, W.C., have issued a price list of a variety of telescopic metal tripods supplied by them. They also stock several ball-heads to fit all the tripods.

The 1907 CATALOGUE, which the Thornton-Pickard Company now offer to post to every applicant, is certainly the most comprehensive history of this progressive firm. In particular, it is welcome for its detailed particulars of the new or improved apparatus now ready for the market. Those who secure it may turn with profit to the new "Royal Ruby Triple Extension" (p. 24 to 30), to the P. new 70s. half-plate set (p. 40), to the still lower priced "College" outfits (p. 46), and to the new "Tribune" camera set sold £1 1s. The Company also give specified descriptions of the new series of "Automan" cameras, of the "Folding Ruby" de luxe instrument, and of the "Focussing Rotator."

THE STUDIO of Mr. J. K. Munro, New Row, Dunfermline, was totally destroyed by fire last week.

THE VERDICT OF THE "TIMES."—In the list of new books in its literary Supplement, the "Times" now includes photography under "Art." The two volumes thus dignified in last Friday's "Supplement" are "Development Made Easy," by A. Horsley Hinton, and "Some Portraiture for Amateur Photographers," by Richard Pinlake.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### FRIDAY, FEBRUARY 22.

- Loughton Photographic Society. "Photography and Things with Digressions." J. T. Ashby, F.R.P.S.
- Cardiff Photographic Society. "Cycle Touring in Brittany and Elsewhere." H. Farr.
- Photographic Society of Ireland. "The Panoramic Camera—Its Advantages and Disadvantages." Walter Scott.
- Sutton Photographic Club. "Variations in Bromide Printing."
- Plymouth Photographic Society. "Enlarging Simplified."
- Skipton Urban District Council. "Enlarging Simplified."

#### SATURDAY, FEBRUARY 23.

- Edinburgh Photographic Society. "Round Africa with the British Association." Illustrated. Hugh Marshall, M.D., F.R.S.
- Hove Camera Club. "An Idyllic Minister." E. W. Harvey Piper.
- Bishop Auckland Photographic Society. "Enlarged Negatives on 'Rotograph' Negative Paper."
- Southampton Camera Club. "Amateur Photographic Prize Slides."

#### MONDAY, FEBRUARY 25.

- Lancaster Photographic Society. "Tabloid Brand Photographic Chemicals."
- Southampton Camera Club. "A Tyrollese Valley." Illustrated. James Shaw.
- Oxford Camera Club. "Pictures of Far Eastern Life." Sir Walter Hillier, K.C.M.G.
- Bowes Park Photographic Society. "Development of Negatives." Part 2.
- Worthing Camera Club. "Second Annual Exhibition."
- Caterham Institute Camera Club. "Contact Printing on 'Rotograph' Slow Bromide Paper."
- Swansea Camera Club. "Enlarging Simplified."
- Lyceum Photographic and Art Society. "Leading Principles in Velox Manipulation."
- Preston Camera Club. "Intensification and Reduction." Discussion.

#### TUESDAY, FEBRUARY 26.

- Royal Photographic Society of Great Britain. "Half-Tone Negatives and a Suggestion for Securing Uniformity in the Same." E. C. Middleton. "The Action of Oxidisers upon the Development of the Latent Image." John Sterry.
- Burton-on-Trent Natural History and Archaeological Society. "Remedying Landscape Negatives by Retouching." J. Holden.
- Keighley and District Photographic Association. "Yorkshire Union Slides."
- Wallington Camera Club. "What can be done with a Hand Camera." C. P. Goetz.
- Rotherham Photographic Society. "Recent Advancement in Photography." H. Wade.
- Leeds Photographic Society. "A Village and District in the N.W. of Yorks." R. Stockdale.
- Stafford Photographic Society. "Flowers and Fruit" Lantern Slides. E. Seymour.
- Darlington Camera Club. "Preparing the Exhibition Print." C. J. Barthorpe.
- Hackney Photographic Society. "Pinatype." A. Rogers.

#### WEDNESDAY, FEBRUARY 27.

- Edinburgh Photographic Society. "The Hand Camera." J. F. Duthie.
- Central Technical College Photographic Society. "Photography with Beck Lenses."
- Edmonton and District Photographic Society. "Competition in Home Portraits." Demonstrated. Messrs. J. J. Griffin & Sons.
- Margate Photographic and Scientific Society. "Rotary Papers."
- North Middlesex Photographic Society. "Permanence in Photography." H. Stuart.
- Borough Polytechnic Photographic Society. "Carbon Work—Demonstrating a Quick Drying Method of Sensitising." H. C. Inskeep.
- Everton Camera Club. "Slumming with a Hand Camera." K. F. Bishop.
- Leicester and Leicestershire Photographic Society. "Platinotype Printing." R. E. Woolmer.
- Acton Photographic Society. "Enlarging Simplified."
- Tring Camera Club. "Sports and Pastimes with the Goerz-Anschutz Folding Camera."

#### THURSDAY, FEBRUARY 28.

- London and Provincial Photographic Association. "Questions and Answers."
- Hove Camera Club. "An Idyllic Minister." E. W. Harvey Piper.
- Dover Institute Photographic Society. "Enlarged Negatives on 'Rotograph' Negative Paper."
- Blenheim Club. "A Trip Across Lapland." Rev. D. G. Cowan, M.A.
- Richmond Camera Club. "Paper by Mr. Cembrano."
- Windsor Amateur Photographic Association. "Marine Photography." F. J. Mortimer, F.R.P.S.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held February 18, Mr. J. C. S. Mummery, president, in the chair. A lantern lecture, "All at Sea with a Hand Camera," was

delivered by Mr. F. J. Mortimer, who, by the aid of a large number of excellent lantern slides, demonstrated the many opportunities for photography afforded by and on the sea. The first part of the lecture was occupied with the photography of ancient and modern vessels of war, the lecturer incidentally drawing some humorous distinctions between the training of the sailor in Nelson's time and that at present in vogue. One example of the modern making of Jack Tar was a photograph showing him occupied in bricklaying. Turning afterwards to yacht photography, the lecturer emphasised the need of a vessel in which to follow the yachts to be photographed. A power boat was an advantage in some respects, but he thought a small sailing boat in competent hands gave the photographer all the opportunity he needed. A high-speed motor boat was useless, on account of the great vibration. The conclusion of the lecture was devoted to photographs of breaking waves, the examples of which obtained by the lecturer, chiefly in the Scillies, elicited frequent and enthusiastic applause.

**SOUTHAMPTON CAMERA CLUB.**—Mr. C. H. Hewitt, F.R.P.S., of the Regent Street Polytechnic, lectured last Monday on "Legitimate Control in Photography." Producing a number of enlarged negatives and positives, the lecturer pointed out the necessities in each case for the handwork upon each. An enlarged positive was then produced, the subject being a vista in Chichester Cathedral, in the foreground of which was a gas standard, spoiling the pictorial effect. With a flexible blade Mr. Hewitt proceeded to work upon the film, reducing it, but the density had entirely disappeared; then, with a retouching pencil, after the medium had been rubbed all over the film to obviate matting, the even tone of the film was restored till the whole form of the standard had disappeared. Subsequently Mr. Hewitt backed another large positive with mineral paper, and showed how, by pencil and stump, the shadows could be intensified, the high-lights accentuated, and the broad effects obtained.

**CROYDON CAMERA CLUB.**—Mr. W. Beck, of Messrs. R. and J. Beck, gave an unusually interesting lecture on "Photographic Shutters" on the 13th inst., the evolution from the crude forms first introduced to modern instruments being clearly shown by means of a series of lantern slides and examples handed round. In early days the "on and off" of the lens cap was frequently relied upon to give short exposures, and with practice satisfactory results were obtainable. The earlier shutters, amongst others, consisted of the "flap," the "drop," the combined "flap and drop," the "rebound," and the "rotating disc." All these were employed in front of the lens, suffered from various drawbacks, and were invariably of most uncertain speed. The "roller-blind" was also early in the field, and still found popularity owing to its good points. Amongst diaphragm shutters, with their equal illumination over the plate, Newman's and Wollaston's would be best remembered. The former, pneumatically controlled, was the first to secure any accuracy of speed, but dust and moisture were apt to alter the readings. The latter, with its crossing sectors, was of high efficiency, and fitted with a highly ingenious friction brake; the exposures had, however, to be estimated by the eye, a most unsatisfactory method for speeds less than 1-5 second. The much-used focal-plane shutters were of high efficiency, but did not give equal illumination all over the plate, and, unless the driving spring was kept constant, inaccuracy of speeds resulted. Its tendency towards distortion was also well shown. The majority of present-day shutters were constructed to work between the lens system, and very beautiful in design and construction some of them undoubtedly were; but, relying on pneumatic regulation, which, as he had already mentioned, was seriously affected by dust and moisture, their marked and their actual speeds differed enormously. In the "Frena" type, including the latest shutter of Messrs. Beck—namely, the "Celverex," the driving tension was kept constant (the spring itself not being made of steel, but of a special metal, having little tendency to alter), the various speeds being regulated by varying the size of the orifice passing close to the diaphragm. These were very accurate, and, relatively to each other, absolutely so. As regards the accuracy of speeds of various types of shutters, Messrs. Beck had tested over 5,000, and a series of such tests were shown on the screen. Taking the highest speeds only, it was instructive to note that with the diaphragm shutters examined, 1-100 second did not in practice realise a higher

speed than 1-50th, whilst those marked 1-250th and 1-300th never approached these figures by one half. Intermediate speeds were generally better, but not invariably so. On the other hand, the roller-blind shutter came out fairly well, the "Celverex" the best of all.

A very brisk and appreciative discussion followed. Dr. Mees, whilst recognising the many good points of the Celverex shutter, said that its efficiency was low at the highest speeds. Exposure might be divided into two classes—(a) the period in which any part of the lens was uncovered, (b) the actual exposures given to the plate, if the efficiency altered with the speeds (a) and (b) were in different ratio. Mr. H. Allen pointed out that the efficiency also varied with the stop employed. Mr. W. H. Smith, speaking as a designer of shutters in the past, one of which fitted to the now defunct Key camera had met with the approval of Sir William Abney, agreed with the lecturer that the method of pneumatic control was extremely faulty, a friction brake generally being just as bad. Mr. F. W. Hicks instanced the splendid work done in the past with shutters of the most primitive description; after all, sound work did not necessarily depend upon elaborate apparatus. Mr. S. H. Wratten well remembered Wollaston's shutter. It worked capitably. Perhaps the simplest shutter of all consisted of a piece of card with a hole in it, passed rapidly in front of the lens by the hand. He had seen some excellent photographs, including slowly moving objects, taken by its aid.

**SOUTH LONDON PHOTOGRAPHIC SOCIETY.**—On Monday, February 11, Mr. H. Creighton-Beckett lectured on "Stereoscopic Photography." In the selection of a camera for this work Mr. Beckett advised one having an adjustable lens panel, so that the separation of the lenses could be adjusted to suit the subject, portraits and near objects being best taken with lenses having a separation of about 2½ inches, while more distant objects and landscapes looked better with a lens separation of about 3½ inches. With a fixed lens panel the most useful separation was one of 3 inches. The lenses should be of about 4½ to 5 inches focus, but lenses of longer focus might be used for distant landscapes. A full exposure should always be given and a soft negative aimed at. A negative with chalky high-lights gave the appearance of snow in the prints. Mr. Beckett gave some useful hints as to printing and transposing. If transparencies were required or a large number of prints he advised the cutting and transposing of the halves of the negatives, but for a few prints the prints were best cut and transposed. In mounting, the best separation of the prints was stated to be about 2½ inches, with about ¼ inch between them, this being the most accommodating in viewing, but the distance between two points should never exceed 3 inches, or eye strain or inability to combine the two pictures would result. A number of excellent slides of Mr. Beckett's own work were shown, and several stereoscopes for the use of members, and a number of fine transparencies, illustrating the work done by the Goerz-Anschütz stereoscopic camera, were kindly lent by the firm of C. P. Goerz.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—Meeting held February 14, Mr. T. E. Freshwater in the chair. The hon. secretary, Mr. H. C. Rapson, demonstrated the making of lantern slides by the wet plate process. His collodion he prepared as follows:—

Low temperature pyroxyline .....	1 oz.
Ether .....	40 ozs.
Alcohol .....	20 ozs.

this making a stock solution. It should be let stand after mixing for a considerable time. Should it get too thick for easy working, it could be thinned down by adding equal parts of ether and alcohol. In winter more ether should be used to obtain equal drying, and in hot summer weather more alcohol. The formula as given above was calculated for a temperature of from 60 to 70 degrees.

His formula for iodising was:—

Cadmium iodide .....	10 grains.
Ammonium iodide .....	80 grains.
Ammonium bromide .....	20 grains.
Alcohol, to make .....	5 ounces.

One part of iodiser was added to 3 parts of the collodion. The cleaned glass was coated by having a small quantity poured in the centre and then run first to one corner and so round the plate, pouring off at the final corner. The plate was gently kept on the rock until the collodion had set, when the plate was ready

transfer to the silver bath, which was one of 30 grains of silver  
trate to the ounce, distilled water being used. Before the silver  
th was taken into general use it was necessary to add a small  
ntity of iodine to it, and this was best done by coating, say, a  
ole-plate and allowing it to stand in the bath for from one to  
o hours. The plate should be gently lowered into the silver  
th by one clean dropping motion. A stoppage was fatal, as it  
ways gave a line at the stopping place. At the same time the  
ate should not be dropped too quickly. For copying from two to  
ree minutes was sufficient to sensitise the plate. The developer

as :—

Iron sulphate .....	1 oz.
Acetic acid .....	1 oz.
Water .....	1 oz.

d just sufficient was taken to cover the plate, afterwards fixing  
potassium cyanide.

Slides could be built up if found too weak, or reduced if too strong  
t ease. The lecturer made, dried, varnished, masked, and bound  
lide, which was shown in the lantern in less than ten minutes.

A series of wet plate slides shown on the screen gave some idea  
the beauty of this process for slide work. A vote of thanks, pro-  
sed by Mr. Freshwater, seconded by Mr. Teape, brought the  
ening to a close

UNITED STEREOSCOPIC SOCIETY.—The London and suburban  
mbers had a very enjoyable evening on Saturday, February 16, at  
e residence of one of the members, Dr. S. Walshe Owen, of Shep-  
rd's Bush. Many unique specimens of ancient stereo-cameras,  
reoscopes, and slides were shown, also a fine collection of hand-  
awn stereographs, produced long before the invention of photo-  
aphy. Before leaving the members awarded Dr. Owen many thanks  
r the evening, which they found most interesting and instructive.

## Commercial & Legal Intelligence.

DISHONEST ASSISTANTS.—At the Highgate Police Court, last week,  
ank Fisher Cuthbert, photographer's assistant, was sentenced to  
o months' imprisonment for stealing from the studio, 80, Stroud  
een Road, Holloway, a camera and three lenses, value £13 15s.,  
e property of Charles Brown, photographer, Truro Road, Wood  
een.—At Bow Street Police Court, on Monday, George Cotmore,  
young man living in Elm Grove, Peckham, pleaded guilty to steal-  
g cameras, etc., worth £19, belonging to Messrs. Houghtons, Ltd.,  
89, High Holborn, by whom he had been employed as a ware-  
useman. The prisoner was sentenced to three months' hard  
ou.

BANKRUPTCY OF AN INVENTOR.—Theodore Brown, 26, Drummond  
ad, Boscombe, appeared for his public examination at the Poole  
nkrupcy Court on February 14, before the Registrar. The  
ement of affairs filed by the debtor disclosed gross liabilities  
ounting to £432 10s. 5d., of which £392 10s. 5d. is expected to  
nk for dividend, and assets estimated to produce £84 8s. 4d.,  
aving a deficiency of £308 2s. 1d. The causes of failure alleged  
debtor were: illness of self, bad trade, and want of capital, and  
enses of advertising. In reply to questions put by the Official  
eiver, debtor first of all explained that he was a specialist in  
ocular affairs in reference to photography, or the science of  
ocular vision as applied to photography. He began in a small  
y at his parents' residence in Salisbury. The Official Receiver:  
u have not confined yourself to the ordinary beaten track, but  
ve tried to take a short cut to fame and fortune by inventing  
orts of clever things in connection with your trade?—Yes. How  
ny patents have you taken out?—About thirty provisional orders,  
I suppose a dozen have been completed and lapsed at various  
ervals. Have any of them taken definite form and shape?—  
s, a few of them. One of my first was an instrument for develop-  
photographs in the daylight. Practically that was a success, but  
merically it was a failure, as the firm who took it up put it on  
market in a form that was not cheap enough for the amateur.  
ntinuing, the debtor said that in 1903 he was joined in partner-  
p by his cousin, and the business was then carried on under the

style of "The Stereoscopic Living Picture Co." His cousin brought  
in £500, "And," added the Official Receiver, "you brought your  
brains and all these wonderful inventions." to which the debtor  
laughingly gave an affirmative reply. In addition to his partner's  
£500 he paid out something like £200 to clear up liabilities, and  
now there was a deficiency of £300. Besides this, he had £400 on  
account of his share in his father's will, so that in two years he got  
through something like £1,400. He had got out an apparatus  
known as "The Theodore Brown Automatic Retoucher," a patent  
which was being worked by a Birmingham firm on a 10 per cent.  
royalty, but he had only received about £10. He was not sur-  
prised to hear that the holder of the patent had refused to give the  
Official Receiver 6d. for it. (Laughter.) He was insured for £250,  
but the bank held the policy as security for his overdraft, and a  
friend was a third guarantee without any security. He was aware  
that by his bankruptcy he had got rid of his interest in his father's  
will, so that the creditors had taken from them any interest in that.  
The examination was closed.

### NEW COMPANIES.

H. KRUGER AND SONS, LIMITED, have been registered with a capital  
of £1,000 in £1 shares, to carry on the business of artists, photo-  
graphers, manufacturers and repairers of cameras and other photo-  
graphic appliances, etc. There will be no initial public issue. The  
registered office is at 26, Queen Street, Huddersfield.

## Correspondence.

\* Correspondents should never write on both sides of the paper.  
No notice is taken of communications unless the names and  
addresses of the writers are given.

\* We do not undertake responsibility for the opinions expressed  
by our correspondents.

### SULPHIDE TONING OF BROMIDE PRINTS.

To the Editors.

Gentlemen,—We were recently toning a batch of Barnet bromide  
prints of various grades. Two of these prints were somewhat dense  
and were slightly reduced in a weak solution of ferricyanide reducer,  
with the addition of hypo. After clearing they were slightly rinsed  
and put into the ferricyanide reducer, together with a number of  
other prints, which had been washed and dried in the ordinary way  
after development. The image of all these prints disappeared in  
the normal way, but on replacing in a freshly mixed sulphide solu-  
tion, the two which had been reduced with hypo and ferricyanide  
quite refused to tone or darken. They were then well washed and  
treated with dilute rodinal developer, but would not re-develop even  
in this.

As the only difference of treatment between these two prints and  
the remainder of the batch (which toned perfectly) was the addition  
of hypo, we think that this may be the cause of the refusal to tone.  
—Yours, etc.

A. DENMAN JONES.

Jandus Works, Hartham Road, Holloway, London, N.

February 16, 1907.

To the Editors.

Gentlemen,—Perhaps, like myself, many of your readers who have  
had trouble with the bleaching—i.e., prints refusing to bleach evenly,  
will surmount the trouble by using the variety of bromide paper  
most suited for the process—to wit, "natural surface."

I have had the same bleaching troubles with all the best makes  
of bromide papers when using the platino-matt variety, but now,  
using same formulæ for developer, fixer (acid or plain), "Wellington"  
formula, or any other bleacher, such as iodine, etc., and sul-  
phide, with a drop or two of hydrochloric acid, I have not had the  
slightest trouble.

"Platino-matt" bromide papers, as the name implies, are made  
to give a "good platinum black," and, unlike the ordinary variety,  
are without the preliminary coating of gelatine, which is a splendid

thing for brightening up the shadows, especially in a toned print. I do not know whether it is this difference that does away with the bleaching trouble, but it is sufficient for me that since using this class of paper I have had no more failures.

So far as gaslight papers are concerned, I only use one kind, "Special Portrait Velox." This, in conjunction with the iodine bleacher, gives a most beautiful tone. I have never had any fault to find with this paper, as far as toning is concerned.

Any of your readers desiring my formulæ and any further information, I shall be happy to address on receipt of a stamp.—Yours faithfully,

S. HALL-DOWNING.

292, South Road, Sheffield.

February 15, 1907.

P.S.—I omitted to mention above that in all cases the prints that failed to bleach all over toned in the parts that did bleach, when flooded with sulphide solution.

### ENLARGING TO DOUBLE AREA.

To the Editors.

Gentlemen,—In the "B.J." of the 25th ultimo a correspondent asks for information as to the size of a plan measuring 9in. x 9in., which he wants to enlarge to twice its size (i.e., area). The following simple arrangement, requiring no calculation, will do what he wants. Take a strip of card exactly 10in. long and about 2in. wide, mark the centre, and then make two clean black lines across the strip,  $\frac{3}{4}$ in. on each side of the centre, that is, exactly 7in. apart. Small pieces of printed matter may be attached at each end, and in the centre, to facilitate focussing, and a few holes for drawing pins completes the arrangement.

In use, pin the strip closely to the copying board and focus sharply, making the two cross lines exactly 10in. apart. The camera is then clamped, and the scale replaced by the plan to be enlarged. The stand carrying the camera is then moved backwards and forwards till the image is quite sharp.

For reducing to half the area, focus the full length of the card strip (10in.), so as to measure 7in. on the focussing screen.

These proportions may be taken as sufficiently accurate for all photographic work.—I am, Gentlemen, yours very truly,

Southfield End, Hanwell, W.

H. J. BURTON.

February 11, 1907.

### PROFITS ON PICTURE POSTCARDS.

To the Editors.

Gentlemen,—I note in your issue of February 8 an extract from "The Amateur Photographer," which "F. M. S." had contributed to that paper. I do not know who "F. M. S." is, but the attitude adopted towards the postcard is practically the same as I had to contend with when first opening with postcards in 1894.

It may interest your readers to know that the first aspect towards the picture postcard was one of contempt, nay, more, defiance. They "would never take on in England," I was told, and stationers to the left and right of me would not touch them. It took not a little persuasion to get the stationery and fancy trade to take up postcards at all.

The attitude of the photographer was always adverse and entirely opposed to the picture postcard, so much so, that in many towns the photographer would not even take negatives for postcard purpose on anything like reasonable terms. The photographer has always turned down the picture postcard as something beneath him, and it is only now, when the business is to a great extent in the hands of large wholesale houses, that he has come to the conclusion that it may be worth his while to do local views and supply them to the stationery trade. However, that anyone should to-day look upon the postcard as not worth doing, is utterly amazing.

Now the question for a stationer to sell 100,000 postcards during twelve months is nothing very wonderful, for a great number of these postcards are sold in sets of six, and this is done, too, in many shops where other articles and goods are sold, and brings into the shop undoubtedly many customers who would not otherwise come in at all. The advantage of such a "bringing-in" line must therefore be apparent to everyone who has anything to do with retail establishments.

My estimate, too, set out of the profit is by no means correct, for

instead of making a profit only of £116 on the penny postcard a turnover of £416 worth of cards, there would be a profit of something like £200, for one lad or junior could efficiently sell postcard and £75 a year for this attendant is not in accordance with what would be paid. This would, at any rate, be reduced by half. Then, again, to charge the whole rent of a stationer's shop, gas, etc., on the postcards, would be absurd. The postcard turnover might represent a quarter or a fifth of the turnover, and thus this £100 would be reduced to perhaps £20.

As to one person having to attend to the buying is absurd. The buyer is generally the principal in these small shops, and takes his share of the profits.

There is no reason why local photographers should not supply stationers with cards, and they are in the very best position to do so, being best able to secure interesting and up-to-date negatives, and if they had only worked intelligently with this end in view, they could certainly have secured the bulk of the local view trade, but have found the local photographer is, as a rule, far from being a smart business man. Of course, he would have to be somewhat speculative, and he might stock some subjects which would perhaps be left on his hands, but the profits he could secure through buying his cards in the first place in the right market, would be ample (with care) to cover his risk, provided, of course, he used sound judgment in choosing his subjects.

As a professional photographer of some many years standing, my sympathies are with the professional. I would be pleased to give any assistance I can to the local photographer by advice or suggestion in an endeavour to get his own back. I am afraid, however, it is an uphill job now—the man in possession is always a difficult man to oust.—Yours faithfully,

F. T. CORKETT.

2, 3 and 4, Cheapside, City.

February 18, 1907.

[While we recognise the force of our correspondent's argument as to the share which the photographer should have taken in the supply of postcards of landscape subjects, we must admit the wisdom of his (the photographer's) hostility to the picture postcard. We may credit him with greater prescience than is due to him, but the development of the postcard trade, particularly that branch of it which includes photographic portraits of celebrities, has undoubtedly cheapened photographs in the eyes of the public, and has thus lowered the prices obtainable by the less skilful professional photographers. Nevertheless, we are glad to have Mr. Corkett's criticism of the figures relating to the sale of postcards, and we shall welcome the views of any readers who have had experience of postcard sales as an appendage to their business.—Eds. "B.J."]

### YACHT PHOTOGRAPHY.

To the Editors.

Gentlemen,—In your current issue is a reply to a querist of "Yachting Photography." As an amateur who devoted many seasons to this work, and developed 12 x 12 plates in his own yacht, and has spent many hundreds in the pursuit, I may say that in filling 12 x 12 plates to the edges with superb negatives of yachts at highest racing speed, and travelling 14 knots, and steaming hard myself, I very rarely made a quicker exposure than 1-50 sec. with aperture  $f/16$ . As this stop is necessary to obtain the required depth of field, quicker exposures are not necessary. I have seen men using 1-150 sec. and obtain images the size of postage stamps, but I worked the size named and 15 x 12, and filled my plates sharply. Yachting photography with large plates is a very special branch, and the most expensive one that I know. When you know how, it is very simple; but you have got to know.—Yours faithfully,

HENRY OWEN (Captain), J.P.

The Quarry, Stourbridge.

February 18, 1907.

THE THIRD ANNUAL Photographic Exhibition and Grand Evening Concert of the Oliver Goldsmith Photographic Society will be held to-morrow, February 23, at the Oliver Goldsmith Schools, Peckham Road, S.E. (corner of Southampton Street). Open at 7 p.m. Concert commences at 8 p.m. Tickets 6d. each. The exhibits will be judged by Mr. E. R. Bull. Tickets may be obtained from the Committee or the Hon. Secretary, J. J. Hearne, 8, Adys Road, East Dulwich, S.E.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

Bragg, Churchtown, Illogan, near Redruth. Photograph named: "His First Cut." Photograph named: "His only Pair."

T. Watson, 76, Anlaby Road, Hull. Photograph of the Hull City Football Team, 1906-7.

B. Collis, Westgate, Canterbury. Photograph of the late Canon Holland.

B. W. AND OTHERS.—In our next.

ARDBOARD MAKERS.—Could you please tell me addresses (or where I could obtain them) of cardboard manufacturers?—W. G.

Thos. De La Rue and Co., Bunhill Row, E.C.; James English and Co., 4 and 5, Radsworth Street, St. Luke's, E.C.; and Halsey and Davison, 15, Carlisle Street, Soho Square, W. You will find others in Kelly's Trades Directory."

V.—We do not know of a twin lens camera of extension sufficient for your purposes. Of the reflector instruments, there are a number which can be recommended to you, the facilities of the instruments being very roughly in proportion to the price. This does not hold in all cases, but we must leave you to judge of the exceptions. For your requirements we should advise you to consult the lists of Adams and Co., Newman and Guardia, Kodak Ltd., Watson and Sons, J. H. Dallmeyer, Ltd., and Marion and Co., and Ross, Ltd.

SAXES.—(1) J. Blundell and Sons, 199, Wardour Street, London, W. (2) A solution of ferrous sulphate added to one of platinum and the mixture boiled will throw down a heavy black powdery precipitate of metallic platinum. The precipitate may be dissolved in aqua regia, the excess of acid evaporated and potass chloride added. It produces a yellow crystalline precipitate with the platinum. (3) Traces only. Alloys of platinum are attacked to some extent by nitric acid. (4) We should advise you to spend £1 on a provisional protection—particulars from the Comptroller of Patents, Southampton Buildings, London—after which you can offer the device to one or two of the large firms whose advertisements of similar apparatus you will see in the "Almanac."

LIATURE.—The instructions for colouring appeared April 6, 1906, p. 262. The celluloid facing is done as directed in the booklet of "Photo-Button Making," issued by Fallowfield.

LYONS.—Better spend £1 on a provisional protection, and then approach one or two manufacturers of amateurs' apparatus.

J. L.—(1) Not equal to a condenser for negatives on the dense side, but quite satisfactory for thin negatives. For all-round work there is nothing to equal a condenser, with which a light, strong or weak, may be used at will. (2) "Albanine" or "Ullmanine" (Penrose and Co.).

ERAS FOR PRESS PHOTOGRAPHY (in reply to "Old Griffo").—The most usual type of camera is the reflector, in which the image is focussed on the ground glass up to the moment of exposure. There are a number of patterns on the market. We advise you to consult the descriptions in the "Almanac." Most are fitted

with a focal-plane shutter, and are arranged to carry dark slides or roll-holders.

FLATTING BACKGROUND, ETC.—(1) In painting a background in flatted oils I have great difficulty in obtaining a perfectly dead surface; my colour on the second coating dries glossy. (2) When getting work done for photographic exhibitions, is it allowed by the judges to work in figures or any other objects by hand? If so, do you think the judges are prejudiced against such additions?—B. T. HUGH.

(1) The second coating should not dry glossy if the flattening colour were rightly prepared and applied. You do not say of what you made it. It should be composed of the colour only, mixed with turpentine, with perhaps a little japanner's gold size to thicken it. As soon as applied the coating should be stippled over with a dry brush. (2) At some exhibitions such pictures would be rejected, and at others possibly not. We should advise you to get a prospectus of the exhibition you propose to show at, and see what the rules laid down are; then, if you have any doubt on the point, communicate with the secretary of the society.

RETOUCHING, ETC.—(1) Can anyone tell me of a really good book on negative retouching, with plates preferred, either to buy or hire? (2) What is the usual summer holiday for studio assistants? We have a fortnight here in summer, full pay all the time, with the other trade holidays as they come, and about three days at the New Year. Is this generally given in studios? I want to make a change to England.—ST. RULE.

(1) "Retouching," by Arthur Whiting (Dawbarn and Ward, 1s.). (2) In most establishments a fortnight's holiday is usually given in the summer, as well as all Bank holidays. There are, however, no set rules in the photographic profession with regard to holidays. Indeed, in some places none at all are given beyond the Bank holidays. Yours seem to be about the average.

ACCESSORY—SHOW CASES.—(1) Where can I obtain an egg, as used by some photographers when taking children, or how is same made? (2) How can I prevent show cases which I have from steaming? I have bored holes in sides for ventilation, but they simply stream with water. The distances from photographs to glass vary from 1 in. to 3 in. in the different ones I have.—EASTER EGG.

(1) We have no doubt that such houses as Houghtons, Marion's, and others that make a feature of photographic accessories would supply you. Better communicate with them. Such things are usually made of papier-maché. (2) If the cases are well ventilated the steam will soon escape when formed.

BLACKENING COPPER.—1. Can you tell me the best and quickest method of blackening copper by chemical means? 2. Also the proper treatment of iron perchloride for photogravure etching?—PHOTO.

1. A. Copper nitrate .....	200 grs.
Water .....	1 oz.
B. Silver nitrate .....	200 grs.
Water .....	1 oz.

Mix A and B, and place the perfectly cleaned metal in the mixture for a few minutes and then heat it. 2. The usual process is to withdraw about 1-20th of the total bulk of the etching bath and precipitate the whole of the iron with ammonia or caustic soda, and to add this precipitate to the remaining 19-20ths of the bath. The solution thus obtained can, if necessary, be made more active by adding a little hydrochloric acid.

DESTROYING HYPO.—Will prints and plates be permanent if washed in water with a few drops of permanganate until the solution keeps its purple colour? A friend of mine who uses this chemical to test dye waters to find if there is any soda in them says there is nothing better.—A. K.

The method can be recommended for plates, but it is liable to cause brown stains on prints, the remedy for which, if they occur, is a solution of oxalic acid.

HAMISH BELL.—"The St. Louis and Canadian Photographer," 3,210, Locust Street, St. Louis, Mo., U.S.A.

**AVONDALE.**—1. The west light is an excellent one to work with, and as you will only be troubled with the sun on the studio late in the day we should advise you to have plain glass. If you find the sun at all troublesome you can have thin tracing linen on light wooden frames that will slide backwards or forwards as required. 2. Art serge is an excellent material for the curtains, it looks nice, and is not at all expensive. 3. Yes, plenty. 4. No; if the studio is constructed according to the plans, you will have a capital one to work in, which, under the circumstances, cannot be improved upon.

**CRYSTOLEUM.**—Please let me know what paper is the best to print on for crystoleum painting. Have tried P.O.P., but have great difficulty in making this sufficiently transparent. Is there a special P.O.P. paper? If so, what make?—E. C.

Albumen paper should be used. Its thin substance is the only one suitable for the process. See the article on page 823 of the "Almanac," 1907.

**E. J. M.**—The amidol formula of Wellington and Ward is as good as any we know. If the negatives are unduly flat the iodide process of the same firm (p. 1065 of the "Almanac") is the best course to adopt.

**A. S.**—The tone is not perfectly permanent, and is difficult to obtain repeatedly, and we should advise you to employ green carbon in preference.

**J.**—Very little practice is needed to work the limelight from cylinders. A firm, such as Archer, of Dale Street, Liverpool, supplying jet and gas, would instruct you in the necessary precautions.

**CAMERA VIGNETTING.**—Can you tell me how to vignette a bust picture outside a camera to get a soft effect?—**LESLIE STUART**

The cause of the trouble is, no doubt, due to the vignetting mask being placed too near the lens, or, maybe, the edges of it are not properly serrated. On page 50 of the Journal for January 18 last, there is a description of "Gardiner's Universal Vignetter." It is a most convenient piece of apparatus, and we should recommend you to procure one. It is very inexpensive, and is manufactured by Marion and Co., Soho Square.

**BACKGROUNDS.**—Will you inform me the best preparation for painting backgrounds? I have an old background which I want to paint white or cream. Should I be able to make a good job of it myself?—**A. E. H.**

If it is painted it will be necessary to flat it afterwards, or the surface will be glossy, and to get an even surface in flattening requires a certain degree of knack. We think, as you appear to be quite a novice at the work, you will be more successful with distemper colour than flattening. You will find an article on the subject on page 82 of our issue of February 1 last, to which you are referred.

**METOL-HYDROQUINONE DEVELOPER.**—Please oblige by saying why every now and again gaslight developer, made as below, should have a brown tinge as soon as mixed and be jet black a few hours after use; whereas on other occasions other lots are water white, and after use have remained for twelve hours open in a dish and only shown a brown stained appearance. Everything kept strictly clean.

Metol .....	3 drachms	1 scruple	} in 200 oz. water.
Hydroquinone .....	11 drachms.		
Sulphite soda.....	16 oz.		
Carbonate soda.....	16 oz.		
10 per cent. bromide potass.	2 oz		

Procedure as follows:—Everything strictly dissolved in the rotation as given in formula. I dissolve the fresh metol Hauff (no discoloured stuff) in 10 to 20 oz. warm water (in a clean enamelled pan kept for this purpose only), then the hydro (purchased in 1 oz. bottles from local chemist; condition, white clean powder, but no maker's name; still, when the solution has been perfect the same make of hydroquinone was used), dissolved in about 10 oz. warm water and added to the metol solution, then the sulphite added from a stock solution (originally dissolved in boil-

ing water, 1 in 3), then carbonate added from a stock solution (1 in 2), then the bromide, and then made up to 200 oz. with distilled water. The same system is followed approximately every time and yet every now and again a make-up goes wrong, as above described. Is it possible the metol and the hydro come together in a too concentrated form, or that the sulphite is not a sufficient preservative? Is there anything wrong in the stock having been made with boiling water, or is it a myth that it loses a lot of power made up thus? I rather fancy this last time it did not colour till the carbonate (ordinary washing-soda always used) was added.—**PIONEER.**

The trouble probably lies either in the use of common distilled water or else the washing-soda, and is due to iron. Distilled water should be used and the sulphite added to the metol, then the hydroquinone. The sulphite should not be dissolved in boiling water, but only warm, and it is advisable to use as much water as possible, otherwise in concentrated solutions the chemical compounds, metoquinone, may be thrown down. Washing-soda is about the last thing that should be used for a one-solution stock developer, as it is never pure, and very frequently contains iron as an impurity. If distilled water and sodium carbonate crystals be used there will be no trouble.

**A VELOX WINDOW-DRESSING COMPETITION.**—Messrs. John J. Gurney and Sons, Ltd., send us the names of the winners in a competition recently organised by them for the best window display of their goods and showcards. The photographic dealers gaining prizes were:—1st Prize, Mr. S. Kitley, 73, Lodge Road, Southampton.

Photograph of the Window Display to which Second Prize was Awarded.

five guineas; 2nd prize, Mr. E. P. White, Park Road, Worthing, three guineas; Mr. Mallinson, 104, Cheriton Road, Folkestone, Mr. E. Ward, of Oxford Road, Manchester, sharing third prize, two guineas. We reproduce a photograph of the second prize display. Mr. Snowden Ward acted as judge.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Professor R. W. Wood has applied orthochromatic photography the "intensification" of paintings in a way which suggests their scenic possibilities. (P. 156.)

Some important conditions as to the use of flame arcs for portraiture are mentioned on page 154.

Some figures and diagrams showing the comparative cost of lighting are given on page 157.

Ammonium hyposulphite has been introduced for fixing in place of the well known "hypo" (sodium hyposulphite), and is said to be preferable in combined baths. (P. 153.)

A device for examining slides at the lantern was shown last week at the Croydon Camera Club. (P. 158.)

Instructions for making backgrounds by the old but little known "wider" process are given on page 155.

The Scottish Salon and the Birmingham Exhibition are reported on page 159.

Something which "has ceased to be photography and has not yet begun to be art" is Mr. H. M. Spielmann's description of some modern photographs, uttered in reference to the recent exhibition at Bond Street. (P. 156.)

## "COLOUR PHOTOGRAPHY" SUPPLEMENT.

Notes on the practice of three-colour print making with carbon are given on page 17.

Dr. E. Stenger, from experiments on the connection between the rate of development and colour rendering, pronounces in favour of ten minutes as the maximum time of development. (P. 19.)

Some further practical notes on photography in colours by the automatic dispersion appear on page 18.

Multiple three-colour back which accommodates changing boxes has been patented in France. (P. 23.)

Some data as to the permanence of pinatype colours appear on page 23.

## EX CATHEDRA.

### Platinum Residues.

The question raised by Mr. G. T. Harris in our issue for February 8 as to the collection of residues, induces us to mention some directions given by Professor Lainer in the current number of the "Photographen Zeitung. Dr. Lainer advises the heating of the old platinum developing solutions and addition of potassium carbonate till litmus paper is only just tinged red; excess of acid is thus neutralised. To the hot solution should then be added ferrous sulphate plus potassium oxalate solutions in the proportion of one of the former to three of the latter. The mixture should at once become black through the separation of platinum, and after allowing some of the precipitate to settle, some of the clear supernatant liquid should be tested with the ferrous oxalate to see whether there is any platinum still in the solution, if so more should be added to the bulk. In chemical laboratories platinum is usually reduced by heating with caustic potash or alkali and alcohol, whereby spongy platinum is obtained. This, together with the use of formate of soda, which is also sometimes used instead of alcohol, is probably, however, far too costly for general photographic purposes. A cheaper and more satisfactory method is that with zinc and acid, as already given in our pages. The process requires no attention beyond an occasional stir up of the solution so as to ensure complete precipitation of the platinum. Magnesium powder has also been suggested instead of zinc, but the latter is, of course, much cheaper.

\* \* \*

### Ammonium Hyposulphite.

Although sodium thiosulphate, or, as it is more familiarly called, hypo, has held its own as a fixing agent ever since its introduction, attempts have not been wanting to find substitutes, which, whilst equally efficacious, should not have the accompanying disadvantages. Most of the suggested salts were, however, either too dear or else did not possess sufficient solvent action on all the silver halides; for whilst one might be perfectly satisfactory as regards the chloride, it would prove but of little use for the more stubborn bromide and iodide. This is very clearly seen from the table of the solubility of the silver haloids, which will be found in the ALMANAC. In 1868 Mr. John Spiller suggested the use of ammonium hyposulphite on the ground of its greater solubility in water and consequent more rapid elimination from both prints and plates. The use of this salt was also suggested by M. Labarre in 1892. The chief obstacle in the way of its general adoption has been, however, its high price, this being approximately about twenty-four times that of the sodium salt. From the above-mentioned table it will be seen that its solvent powers are practically the same as the sodium salt. We now learn, from a brief note by Baron von Hübl in the "Wiener Mittheilungen,"

that it has been introduced, commercially, at a low price both in Germany and Austria. One of the chief advantages emphasised by von Hübl is the rapid fixation in combined baths, one of the most important points as regards permanency of the image.

#### Lenses as an Investment.

Fifteen or twenty years ago, it was a somewhat common observation that a lens by a first-rate maker was always worth a very good proportion of its original cost. That was in the days when, for all-round work, the rapid rectilinear or rapid symmetrical reigned supreme. The modern anastigmatic equivalents of these lenses have no doubt an equally good second-hand value within a few years of purchase. Improvements in lens design and construction are now so rapid, however, that many of the earlier anastigmats are already as obsolete as the rectilinears of the best makers. drawn. The effect of this progress in design and construction must naturally be the decrease in value of such older pattern lenses as are in the hands of photographic workers or dealers. At the same time, progress is a law of life, and the admirable lenses placed at one's disposal by all the great optical firms are almost universally appreciated. While there may be a depreciation in the second-hand value of certain lenses, there is, of course, no decrease in their utility. What they have done for their owners in the production of negatives they will continue to do. Further than this, many of these older patterns may be obtained, in some cases quite new, at substantial reductions, excellent lenses thus being brought within the reach of the worker who possibly has hitherto had to deny himself the advantages their use confers.

\* \* \*

#### The Effect of Lights on the Sitter.

As we pointed out more than once, the effect of the light upon the sitter is a very important matter, and one frequently overlooked by those who have no practical acquaintance with portrait work. The effect is two-fold, the actual comfort of the sitter, and the appearance of the sitter as seen by herself, and, more particularly, her friends. The strong yellow light of a flaming arc is, without doubt, more trying to the sitter than the enclosed arc light or even the open arc, and a trying light is more or less certain to influence expression and thus to militate against the success of the portrait. Also the appearance of the sitter during the sitting has a very great effect on the degree of satisfaction which will be subsequently felt when the proof copies are submitted. This is a purely psychological matter and the ordinary open arc undoubtedly scores here, for the effect is always to enhance the appearance of a pretty sitter and a pretty dress. The sitter's feminine friends make complimentary remarks (without in the least meaning them) and will observe what a loss the stage has suffered, and, thus, thoroughly pleased with the whole affair, the sitter is prepared to like the proofs. For this reason the mercury-vapour lamps can hardly be used satisfactorily unless with them is employed a cluster of ordinary incandescent glow lamps to supply the orange and red rays, in which the lamp is deficient. This is quite an easy matter, and we have recently seen a mercury lamp with tubular incandescent lamps placed between the mercury-vapour tubes.

LIVERPOOL A.P.A.—The annual report of the Liverpool Amateur Photographic Association shows that energetic body to have added forty-two members to its roll during the year, making a net increase of twelve in the number of members. The Society has held a series of "one-man" and other exhibitions during the year, and shows a balance on the year's working for the first time for several years past, and has increased its reserve fund from £22 in 1905 to £40.

#### FLAME ARCS FOR PORTRAITURE.

THE idea of using a yellow light for portrait work, employing with it a plate sensitised for the yellow and orange rays, is by no means new. Variations in the character of the light, either by the use of coloured glass in the operating room, or by the employment of artificial light of one form or another, have been experimented with many times. It is therefore not at all surprising that in view of the increasing popularity of the flame arc lamps for street and shop-front illumination, it should have occurred to some that they might be used for portrait work with colour sensitive plates.

To suggest this use for flame arc lamps, however, and to work out the details for actual practice, are two very different matters. The one is obvious, the other will require close attention to many points, and in all probability many actual improvements, or at all events modifications, in the lamps themselves, before they are suitable for installation in a portrait studio. As this matter has recently been referred to in our columns, it may indicate some of the points in the flame arc lamp which will need attention if they are to be adopted for this special character of work. One of the advantages of these lamps is that, broadly speaking, they will run well through a considerable range of arc voltage, and the various makers supply substitutional resistances, transformers, and other accessory apparatus, so that flame arc lamps may be used on most circuits, frequencies, and pressures. It is therefore possible, as our contemporary "Electrical Engineering," points out, to burn as many as twelve lamps across 460 volts, and a single lamp of less than 50 volts, or, per contra, nine or ten lamps can be put on the 460 volts, and will work with longer average proportionately higher candle power.

This capability of running on a low voltage or running in series in such a way that there is the minimum of loss through absorption of energy in the resistance means that economical working as far as current goes is obtained, but it also means that the light is very apt to flicker unpleasantly. For instance, slight variations in the composition of the carbon, which are almost unavoidable, have very little effect where there is considerable reserve of energy, but when the lamp is running on a minimum the light is constantly fluctuating. It is conceded by electrical experts that flame arcs are as yet too unsteady for indoor illumination, and a light which is not pleasant enough for use in rooms is hardly likely to be considered steady enough for the rather more nervous trying occasion of a portrait sitting.

Another important point to which the attention of photographers must be called, especially those whose studios or operating rooms are small, is the extent of fumes and dust produced by these flame arc lamps in general. The acid gases are likely to have a serious effect on the mechanism of the lamps themselves, notwithstanding the arrangements provided for the ventilation of the lamps. The earths employed in the manufacture of the cored carbons very readily volatilise, and as readily resume the solid form, hence the dust and dirt. We have referred in "Ex Cathedra" to the increased carbon consumption with flame arc lamps, and to the generally high cost of flame arc carbons, so that we need not now emphasise this.

Our readers will see, therefore, that much more needs to be considered; the matter can be summed up under the economy of current and gain in colour-rendering. Steadiness and pleasant quality of light, and freedom from dust and dirt in the studio, are certainly desirable, while depreciation of lamp mechanism and the necessity for special ventilation will naturally increase the cost of running a flame arc installation.

## BACKGROUNDS BY THE POWDER PROCESS.

[In the following article instruction is given in the use of a process for the preparation of backgrounds, which is little known at the present time, but which may be found of service by photographers requiring to extemporise a background quickly, or provide one of a special character.]

In a previous article the method of making backgrounds by the distemper method was fully described. It was there mentioned that a certain knack in working was necessary in order to avoid streaks or brush marks that may show strongly when the work is finished. It may now be added that the worker need not be disheartened should he not succeed in his first attempt, he will naturally recognise the cause of his failure and be able to avoid it in the future. I here propose to describe another method of producing backgrounds that is far more simple than the previous one, yet it seems to be but little known amongst photographers, who may desire on occasion to make their own backgrounds. It goes without saying that by whatever method backgrounds are made, more trouble and mess are involved than purchasing them ready-made; and good ones are now to be had at a very low price as compared with that charged for them some years ago.

### An Old Secret Process.

The method now to be described was some years ago sold as a secret process by one of the leading London photographers—wit, the late Mr. Robert Faulkner. It is sometimes called the powder process, inasmuch as the pigment is applied to the canvas in powder form. By it graduated, or cloudy, effects are easily produced, which is no easy thing for the novice to do either the distemper or the flatted oil methods. With the powder system the novice should succeed in his first essay, if the instructions are followed.

For the fabric, that which was recommended for the distemper method is the best—namely, unbleached sheeting.\* It is well, however, to have a thicker quality than is really necessary for distemper. The frame upon which the fabric is strained need not be of the same substantial character as advised in the former article, as there will be less shrinkage in the canvas when dry. In fastening it on the frame, for that reason, it should be strained somewhat tighter than is permissible with distemper. The canvas does not require sizing; indeed it must not be sized, will presently be seen. The background being thus far prepared we take common whiting and drop black, with or without some Venetian red, in powder. The latter is to give a warm tint, should that be preferred to the cold grey given by black and white alone. No definite proportions can, of course, be given, as they must depend entirely upon the colour required. When a mixture of the desired colour is arrived at, about one-third to one-half its weight of common dextrine is added, and the whole again very intimately mixed together. It is well to pass the mixture through a sieve, to ensure the removal of any small lumps of either the white or the black, which, if present, would cause trouble when the colour is applied. The colour, being thoroughly mixed, is ready for use.

### To Apply an Even Coating.

To apply it, the canvas must be evenly wetted all over; not merely damped, but made thoroughly wet. The best way of doing this is to lay the frame on the ground and then water it with a garden watering pot. The frame is then reared up on end, and the superfluous water allowed to drain out. This part of the work is best done out of doors, so as to save mess inside. After excess of water has drained away the background is taken

inside and laid flat upon the floor. The dry powder is then pretty evenly distributed over the surface: this is best done by sifting it over from a sieve. All that now has to be done is to work the colour well into the canvas with a stiff brush. The most suitable brush for this purpose is an ordinary clothes-brush with a handle. The brush should be used with a broad circular motion, working the pigment well into the fabric. If, when the brushing is finished, any portion should appear thinner of colour than the rest, a little more of the powder should be sifted on those parts, and the brush vigorously applied again. If, when the background is dry, should any unevenness show (which will not be the case if the directions have been followed), all we have to do is to wet the canvas thoroughly again and repeat the brushing, with perhaps a little more colour. It may possibly happen that the background, when finished, proves a little darker, or maybe lighter, than anticipated; but that is easily altered by once more wetting it and sifting over some darker or lighter powder, and then repeating the brushing.

### Shaded and Hatched Backgrounds.

So far, we have assumed that a uniform flat background only is required. We will now suppose a shaded or clouded one is desired—say for vignettes. In this case, after the colour for what may be termed the ground work has been prepared, two or three others are mixed with different proportions of white and black. Then, while the canvas is still wet, some of the darker grade is sifted on where the dark colour is required, and some of the lighter where it is desired that the tint should be lightest. The tints are then blended by brushing as before.

One of the objects of the invention of this method of making backgrounds was the production of scenic ones, and well adapted it is for the purpose in the hands of those with a certain amount artistic ability, and, of course, some knowledge of drawing. The process is carried out as follows:—Several grades of colour—black and white—with dextrine are prepared. They are then kneaded into a stiff dough with water, and made into thick sticks or rude crayons and allowed to dry. Then while the canvas is still wet, or it may be re-wetted if already dry, the design is sketched in with the dry crayons. The sketch-in lines are then softened with the brush, lightly used and with a circular motion.

A clouded background for vignettes of the Richmond head style, introduced by the late Mr. Sarony some years ago, may be readily made by hatching some bold black lines with charcoal or black crayon, made as described above. In this case it is not desirable to soften the lines by brushing, as they should, of course, appear somewhat pronounced in the picture. The background, being out of the focus of the lens, is sufficient to prevent extreme harshness. Should a background, made by the powder method happen to be wetted, say, from a leaky roof, it is not necessarily spoiled, as a distemper one might be. All that has to be done to repair it is to wet it evenly all over and then give it a good brushing, with the addition, perhaps, of a little more of the powder colour. In conclusion, I would emphasise the point that in making backgrounds by this method the pigments should be worked well into the substance of the fabric, and not be confined to the surface only.

WILLIAM MICHELL.

\* "B.J." February 1, p. 82.

THE LATE MR. B. BARRY.—The death is announced at the age of seventy-seven, of Mr. Bartholomew Barry, of 11, Barking Road, Canning Town. Deceased, who carried on business as a photographer,

had had a long and painful illness. He had had a varied career, in the Navy, and afterwards in the Mercantile Marine Service. He was a member of the Municipal Alliance in Poplar.

## THE OPTICAL INTENSIFICATION OF PAINTINGS.

THE following article by Professor R. W. Wood, of the John Hopkins University, Baltimore, which we quote from the *Scientific American*, suggests a new application of orthochromatic photography which has obvious possibilities in the effective presentment of paintings such as is commonly done when a striking work of art is sent on tour round the country.

One of the great difficulties which the artist has to contend with in representing scenes in which great contrasts of luminosity occur is the comparatively narrow range of luminosity obtainable on canvas with pigments. According to Aubert, the whitest paper is only fifty-seven times as luminous as the darkest black paper, and this probably represents about the range obtainable in paintings. Contrast with this the enormous range of luminosity in a sunlit landscape, where the high-lights are many hundred times brighter than the deep shadows, to say nothing of sunset views, where the disc of the sun itself is to appear in the picture. As is well known, the colours of natural objects change in tint as the illumination is increased, green becoming yellowish, for example; and artists, by taking advantage of this circumstance, consciously or unconsciously, are able to suggest a high degree of illumination without actually reproducing it. Pictures are sometimes improved by strong local illumination; anyone who has spent much time in sketching must have frequently noticed what pleasing effects are sometimes produced when a ray of sunlight, filtering through the trees, falls upon that portion of the canvas which represents, say, a sunlit meadow. Noticing effects of this kind so frequently, I have been led to experiment with carefully graded illumination, and have obtained results of remarkable beauty. If we can produce a strong illumination on all of the high-lights of the picture, and a feeble illumination on all of the shadows, we shall obviously greatly increase the range of luminosity. This may be done by a very simple means. We have only to take a photograph of the painting on an orthochromatic plate, preferably on a red-sensitive plate with a suitable ray filter, make a lantern slide from the negative, and project this picture, not on a white screen, as is usually the case, but upon the original painting. The experiment is to be made in a darkened room, of course.

Effects of a very startling nature are produced in this way, especially in the case of moonlight and sunset pictures with fine cloud effects. The most striking, and artistically the most pleasing, subject which I have yet tried is a little pastel of the market-place in Concarneau (Brittany) by Bullfield, which is a wonderfully sunny picture. Under the graded illumination of the lantern the picture becomes filled with a perfect flood of sunlight, and we feel at once that here for the first time we are looking at a picture in which the enormous luminosity contrasts of nature are really approached. If after looking at the picture illuminated in this way for a few minutes we remove the slide from the lantern, allowing a uniform illumination to fall upon it, we feel a decided shock. The picture

looks as if it had not been dusted for ten years, the sunlight leaves it, and everything looks flat. As we become accustomed once more to the usual illumination, the appearance of the picture gradually improves. It is most curious, however, to note how a short view of the painting under the light of the lantern educates us at once to a higher standard of luminosity contrast, so much so, in fact, that when we change suddenly to ordinary illumination the picture at once strikes us as a very feeble attempt at anything like correct values. The effects are very different, according to whether we take our negative on an ordinary or on an orthochromatic plate, especially if there is much blue in the picture. We can in this way alter the relation of the values in the picture, and study the effect.

It is my opinion that if the values are correct in the original painting, they will hold under the graded illumination produced by the lantern. If they are not right, the errors will be glaringly magnified. As yet I have not had an opportunity to experiment with many pictures, but the method is so easily carried out that anyone having a good lantern can repeat the experiment.

If the picture contains patches of bright, pure red, and a red-sensitive plate is not available, it is a good plan to touch up the negative, as otherwise the illumination of these patches will be too feeble. Any desired effect can be secured by local reduction or intensification of the negative or lantern slide. We can in this way experiment to our heart's content with a painting, altering the values at will without injuring it in the slightest. A most curious effect is obtained if the negative itself is projected upon the painting. This, of course, lessens the contrast, and if the negative is a fairly dense one, it may destroy the contrast almost entirely, making the picture look like an almost flat wash of chocolate. This experiment is instructive only as showing how completely the values in a picture can be controlled by local illumination.

The method is, of course, of very little practical importance, though a small exhibition of suitable pictures illuminated in this way would be well worth attending. Each picture would have to be illuminated by a separate lantern, of course.

In repeating these experiments, the only difficulty which will be found is getting the lantern picture "into register" with the painting. In taking the negative, care should be taken to have the painting exactly vertical, and the lens of the camera directly in front of its centre. The same conditions should obtain during the illumination of the painting. It takes some little practice to get the projected picture exactly the right size. The best plan is to select two conspicuous objects, and note whether their distance apart is greater or less in the projection than in the painting. If the former is found to be true, the painting should be brought nearer to the lantern, the focus being changed, of course.

Very likely scenic effects on the stage could be heightened by employing this method of illumination, or some modification of it.

R. W. Wood.

### PHOTOGRAPHY AS AN ART.

AN echo of the recent exhibition of "modern photographs" in the galleries of the New English Art Club is supplied by the article in the "Morning Leader" of February 21, wherein Mr. H. M. Spielmann compares the products of the camera with the painters' art.

"Now, this exhibition is very interesting—as photography. We have superb portraits by Mr. Craig Annan and the rest which, if we don't want to know the colour of skin and hair and eyes, are invaluable as giving with perfect accuracy the man or woman as seen by the camera's one eye. As seen, mind, in front of the lens; not as the artist sees the sitter, seizing the finest and most characteristic expression as it flits across the face at a transient moment, during, or, maybe, before or after, the formal sittings, and then quietly laid upon the canvas. Thus Watts painted portraits; thus the finest photographer cannot take them, unless—no thanks to him—he be lucky and the sitter an accommodating genius. We were told in "The Colleen Bawn" that "the photographic apparatus cannot lie"; but think of the splendid negatives taken of yourself—splendid as photographs—which you have nevertheless denounced as "not a bit like." Why, Mr. Coburn's fine photograph here of

Mr. Bernard Shaw shows him as a serious-minded man, incapable of writing "pour épater les gens" and scorning to pull the public's leg. You can't depend upon the photographic process. At the same time, as photographs, there are portraits here by Mr. Holland Day, M. Demachy, and Mrs. Käsebier, which, if we assume them to be good likenesses, are hardly likely ever to be surpassed in the qualities they display.

"But think of the head of Christ by Rembrandt in the Louvre, with its real, its vivid expression of profound and far-away vision, and then look at "The Seven Words," by Mr. Holland Day, with their make-up of crown and thorns—and give the answer yourself. The made-up pictures are devilish clever, no doubt; so, too, are the tricked-up landscapes and the like, with composite printing, their suppressed bits, their double printings out of register, and so on, and sometimes tampering with natural light and shade; but while we may admire the results and offer the meed of our well-deserved applause, we cannot escape the feeling of insincerity in the whole, so far as these passionate claims to consideration as Fine Art are concerned.

"It is, of course, natural enough that the pendulum should swing back, and that, after the period in which painting has derived so much advantage from photography, photography should imitate

inter-methods and aspire to a place near, if not beside, painting. Not satisfied with its unchallenged claims to truth, accuracy, perfection of detail, and authenticity, it is now demanding to be considered as an art, and to claim artistic individuality for its practitioners, who would be accepted as artists capable of impressing the genius of their personality on the bichromate-gelatine process.

It seems to me that photography is to art, as a method, much as the pianola is to the piano: the machine can be perfectly controlled; light and shade, phrasing, and the like can be expressed by skilled persons; but those "clumsy tools," the human hands, of derewski, working straight from the player's soul, will always try it off—*Sharis contradicente*—over the bellows and hole-stamped roll of the mechanical piano player.

But when photography is content to be itself, and does not aim at aping, or, rather, impersonating, something else its votaries will give the applause and gratitude of the world. So long as it depends, as it ever must, on an entirely scientific and mechanical basis, it cannot claim to be one of the Fine Arts. The model, which the artist is a convenience, a servant, to the photographer is a master, if not a tyrant, to be cajoled and coaxed chemically to his ends. And even when most successful, a photographer can never be nearer to a painting than a monochrome drawing (*pace* Shaw). At that time the print has perhaps ceased to be photography, and has not yet begun to be art.

COSTS OF LIGHTING SYSTEMS.

The following notes and table (the latter due to Mr. Claypoole) are taken from a recent paper by Mr. James Swinburne, F.R.S., before the Association of Engineers-in-Charge:—

It is very difficult to make any useful comparison of the costs of various illuminants, as each has special advantages and draw-

backs. However, the cost per candle-power in payment to the supply company is not difficult to get at. The accompanying figure gives a great deal of information in a graphic form.

It tells you how many candle-powers you can get for 1s. from various illuminants. Thus, if electrical energy is at 5d. per unit, a carbon filament will give you, roughly, 500 c.p. hours, say, 10 candles for 50 hours for 1s. paid to the supply company. If the electrical energy is 3d. per unit, as at the bottom of the diagram, 1s. worth of energy will give you 2,000 candle-hours with a metallic filament lamp, say, 20 candles for 100 hours; or with a mercury vapour lamp you can get 8,000 candle-hours, or, say, 100 candles for 80 hours. A flame arc at 4d. per unit, again, gives 10,500 candle hours for 1s.; or, say, 1,050 candles for 10 hours.

Turning now to the gas diagram, you find that if gas is at, say, 1s. 6d., a flat flame burner gives about 1,400 candles for 1s., and so on. The incandescent burner, however, gives over 3,000 candle-hours for 1s. at 4s. 6d., that is to say, on the top line. This might be, for example, 60 candles for 50 hours. At 3s. 6d. it gives about 4,000, and so on. Oil lamps have been taken for one price of oil only, 8d. a gallon, and acetylene, with carbide, at 6d. per lb.

These figures take no account of the costs of renewals of electric lamps or mantles, or of trimming and providing globes for arc lamps. They, therefore, do not really give a comparison of the costs. Moreover, the lamps and mantles are taken as new. All the same, the figures are very instructive. It will be seen that oil lamps are much cheaper than either ordinary electric carbon lamps or gas with ordinary burners; and acetylene is astonishingly cheap.

As far as cost of gas and electrical energy go, it is not difficult to compare the rivals, but it is much more difficult to compare the cost per candle-hour, including lamps and mantles and incidental expenses. Broadly, we may say that gas lighting with mantles is very much cheaper than any form of indoor electric light, except the mercury lamp.

MULTIPLE COLOUR ILLUMINATION IN MICROSCOPY.

In our issue of February 8, the use of the special "M" screens, prepared by Messrs. Wratten and Wainwright for photomicrography, was fully described. Utilising the same principle for visual microscopy, much more perfect and sharper definition can be obtained. We are indebted to Mr. Rheinberg, who has made a special study of this subject for the past ten years, for copies of his articles, from which one may glean the following practical details.

The advantages of this method of illumination are (1) increased ability to see objects, and (2) increased ability to draw conclusions from what is seen, or, in other words, the nature and form of structure are better produced.

There are three methods of using this colour illumination:—(1) the refraction method in which the colour disc is preferably placed in the diaphragm holder of the sub-stage condenser, with an objective of low or medium power. As in dark ground illumination, the colour of the central portion of the disc becomes the colour of the background; an object placed in the field is illuminated by the light which passes through the peripheral portion of the disc, so that by using a central disc of one colour, and a peripheral ring of another colour, the object appears of one colour against another coloured ground.

For high power work, the second or diffraction method is employed with objectives of high or medium power, and the colour disc is placed above or between the lenses of the objective and the light transmitted by the sub-stage condenser cut down by the iris diaphragm to a narrow cone which just illuminates the central portion of the colour disc, leaving the surrounding part unilluminated. The colour of the central portion is therefore again the only one which lends itself to the colour of the background. When an object is placed in the field it diffracts the light incident on it, changing each ray into a number of rays spread out at various angles from the point of impingement. The greater part of these rays pass through the peripheral portions of the colour disc and cause the object to assume this colour.

The third or composition method is based on the fact that white light is composed of all colour and that different colours can be combined to form white. The colour disc, with two complementary colours, is placed in the diaphragm holder of the sub-stage condenser, and by gradually closing the iris diaphragm, the relative quantities of the coloured lights is altered, and thus approximately white light can be formed. The background then appears uncoloured. But when an object is placed in the field, the light thrown up by it into

the objective is not mixed in the same proportions to form white. The ridges, etc., catch up more of the oblique coloured rays, and the finer and more transparent parts pass more of the central portion, therefore the object appears in various shades of the two colours on a white background.

Specially prepared screens, according to Mr. Rheinberg's method, are prepared by Messrs. Wratten and Wainwright, but it is obvious that anyone can make them by using their "M" filters.

Utilising Mr. Rheinberg's principle with the "M" screens, one could utilise as complementaries, the A and B, E or G and B, these would be red and green. For yellow and blue, K3 and H or C, or D + H and B + E. These are but examples. Others can easily be picked out either by practical trial or examination of the table of transmissions of these filters on page 101, bearing in mind that white light is approximately formed by complementary colours, which are roughly red and green blue, orange and greenish blue, orange yellow and turquoise, yellow and blue, greenish yellow and violet blue, green yellow and violet, yellowish green and purplish violet, green and purple, and emerald green and reddish purple. All these colours can be compounded by using one or more screens combined, as given in the table of monochromatic transmissions on p. 101 (second column).

#### A HANDY CONTRIVANCE FOR LANTERNISTS.

Those familiar with working a lantern are aware that the escaping light through the sides and back can hardly be considered an ideal illuminant for reading titles, identifying spotting, etc. At last week's meeting of the Croydon Camera Club, Mr. W. H. Smith, Past President, showed a simple little device of his own design for lightening this task. This is illustrated in the cut in reduced scale, and consists of a rectangular tin box, the top and sides (A A) having ground glass set in. The side light enables the spots and title (if any) to be easily seen, the top light allowing the slide to be examined comfortably. A night light occupies the position shown.

Dealing with night light and candle methods of illumination for

ruby lanterns, Mr. Smith said that the ordinary wax candle would rarely stand the heat evolved, unless the lantern was very large and exceptionally well ventilated. Candles generally guttered freely, and too frequently assumed an attitude of obeisance, hardly conducive to proper burning, or good temper on the part of the operator. He had recently tried a hard candle named "Cyclites," made by Messrs. Field and Co., of Lambeth. It rejoiced in a most upright character under trying conditions of heat, and appeared admirably adapted for the purpose indicated. The same firm also made a capital little lead-cased night light for photographic purposes.

**FALLOWFIELD'S ANNUAL SALE.**—Messrs. Fallowfield, 146, Charing Cross Road, London, W.C., commence on Monday next, March 4, the annual sale of apparatus and materials which are soiled but otherwise in good condition. A selection from their list appears among our advertisements this week, but the full list itself, which will be ready to-morrow (Saturday), should be applied for.

#### A GERMAN PATENT FOR A THREE-FILM PLATE.

DR. FRANZ STOLZE, of Charlottenburg, Berlin, has been granted a German Patent (No. 176,679, August 31, 1905) for a triple film plate, intended for direct three-colour photography without filters. For three-colour work experiments have been made to expose simultaneously with one lens three films of emulsion lying one behind the other, in which the top one is principally sensitised for indigo blue, the middle one for green, and the lowest for orange red. But up to the present all the sensitised emulsions are useless, as the upper films of emulsion, even without being coloured, absorb the required colours, and act as filters for those lying underneath. The action of the emulsions hitherto used is especially detrimental to the lowest film sensitised for orange red. One must therefore use quite different kinds of emulsions for the three-colour films, or at least for the two upper ones. They must be so made that, as light-filters, they are transparent for the colours corresponding in correct ratio to the orange red sensitive nerves, thus when looked through they must transmit orange red and then still less red, yellow, and green. Experiments have proved that this is the case when the emulsion, without being sensitised with a dye, appears orange red by transmitted light. Every other kind of light will be the more completely absorbed the thicker the film of emulsion is, or the more thin films are superimposed. The top film will transmit then red, orange, yellow, yellow green, and blue green, and the middle one, which is sensitised for green by a red dye, which also acts as a filter, transmits red, orange, yellow, and yellow green. As the third film is made opaque for orange by a sensitiser, the three films will together use up practically all the light, which is active in photo-chemical action, and only transmit very little. The claim made for the invention are:—Superimposed negative films for simultaneous three-colour photography with one lens, the chief point in which is that the emulsions used for at least the two upper films, shall, without sensitising with a dye or insertion of a filter, appear orange red by transmitted light.

#### THE SCOTTISH FEDERATION.

##### ANNUAL MEETING.

ON Saturday, February 23, in the Lecture Hall of the Paisley Museum, the annual general meeting of the Federation was held under the presidency of Mr. S. Stewart, Vice-President. There was a large attendance, including about fifty delegates from the societies. Some extracts from the Secretary's report are as follows:—

The past season has been one of quiet prosperity. We closed last year with thirty-eight societies, and, after deducting three societies dead and one resigned (although probably these should be deducted from 1907), we close the year with thirty-eight societies; and it might be mentioned that another two have federated for 1907.

The portfolio has been energetically and successfully engineered by Mr. Hill, who has given to it a whole-hearted devotion that is apt to put to shame some of our more leisurely movements. The entries have increased, and I think interest in the Portfolio is being developed.

The lantern-slide entries show a diminution in numbers this year, although those who take part in it show no waning enthusiasm. I must give all credit to that busy man, Dan. Dunlop, for his management of the Lantern Slide Section.

"The Blue Book" is a valued companion to associates. Year by year I am vain enough to think it improves, but I do not think it has reached finality. One important point is that it must be kept small in size—waistcoat pocket size, in fact—so that it may be always available. Its aim should ever be *multum in parvo*.

"The Secretary's Letter" is welcomed monthly by associates. One proof of this is that if a parcel goes amissing on the railway I am not long in getting word of its disappearance. Thanks are due to the associates whose contributions have enlivened its pages.

The excursion to Loch Lomond was thoroughly enjoyed by those who took part in it. Messrs. Horn, Morren, and Crockett deserve our thanks for their very complete arrangements—they even negotiated with the Clerk of the Weather for a sample of his best.

Our staff of lecturers, demonstrators, judges, etc., is a most valued possession. There are few of our societies but have had the benefit

of the services of these gentlemen. Our best thanks are due to the self-denying labours of these gentlemen.

Everything shows that the federation remains true to its trust, and through its various agencies does its best for the betterment of photography in Scotland.

Mr. Hill appealed for a more whole-hearted support to the Portfolio, especially from the better known workers. It should really be, he said, a travelling salon, and it deserved every support. Mr. Dunlop called upon associates not to neglect the lantern-slide competition, the number of societies sending in entries was out of all proportion to the number of federated societies.

The Treasurer showed a satisfactory financial balance in his annual statement.

An enthusiastic invitation from the Aberdeen societies to hold the 1908 Salon in Aberdeen was unanimously accepted.

Office-bearers were appointed as follows:—President, Lord Provost Sir Alex. Lyon, Aberdeen; Vice-Presidents, Robert Milne and S. Stewart; Secretary, John B. Macdichan, Blairgowrie; Treasurer, Arch. Campbell; Auditors, J. A. Murdoch, C.A., and R. C. Thomson. Council:—Henry Coates, Fred. W. Kay, G. L. Smith, J. B. Philip, James C. Baird, Dan Dunlop, J. W. Ross, E. Darwin Wilmot, A. Symon and James Patrick, Mr. Patrick being elected as an associate member.

It was unanimously agreed to accept an invitation from the Brechin Photographic Association to hold the annual excursion to Edzell.

A suggestion to restrict the number of each person's entries to the Salon was defeated.

#### THE SPIDER'S WEB AS A NEGATIVE.

To one on a vacation and interested in photography (writes a correspondent of the "Scientific American"), the good part of a day may be spent in collecting and printing cobwebs. The process is easy. Let him get the farmer's potato sprayer, put in it some "sizing japan," thinned with turpentine and coloured from a terra-cotta tube. Then let him take some old window glass, or a few cleaned negatives, and go in quest of a clear web with a good centre. He will find it on an outbuilding or fence in the open. When found, let him spray it, then bring up a dry plate of glass behind it and lift it from its moorings. In a couple of hours the web will be dry, and so hard that the plate can be washed without any injury to the web. From plates thus secured he may make prints to his heart's content. To make combination pictures, put the plate over any clear negative and print through both of them. For printing the webs themselves, blue-print paper may be used to advantage, inasmuch as it simplifies the work.

In finer experiments I have tried dyeing the web, spraying it with tincture to make it opaque, then taking a fresh damp negative which had previously been exposed to the light and washed in a hypo bath, to lift it. The filaments of the web were so fine, however, that though perfectly preserved, it was impossible to make a print from it. So that for photographs I will stick to the enamelling process—that is, to spraying with "sizing japan." The japan is the same as used for gold lettering.

**THE LATE MR. W. B. SCOTT.**—We regret to announce the death of Mr. W. B. Scott, who passed away on February 9. Mr. Scott carried on the business of Brown, Scott, and Co., mount and frame makers, of Red Lion Yard, High Holborn, which was established in the year 1869.

**THE B. J. EDWARDS LANTERN-SLIDE COMPETITION.**—The following is the list of the prize-winners in the competition organised by Messrs. B. J. Edwards, of Ealing, in connection with their "Krystal" plates:—James Shaw, Manchester; Edgar B. Bull, Forest Hill; Alex. H. Paterson, Sutton Coldfield; A. G. Thistleton, Manchester; Kenneth Bishop, Warrington; T. H. Blake, London; H. Cochrane, Junr., Belfast; J. Shaw, Manchester; William Rees, Amsdale; G. A. Booth, Preston; Ellis Kelsey, Eastbourne; J. C. Miller, Leek; H. E. Corke, Levenocks; Miss Kate Smith, Watford. Honourable Mention:—H. van Wadenoy, Barry Dock; H. Hill, Sheffield; A. J. Linford, London; A. W. Searley, Kingskerswell; R. R. Bull, Forest Hill; J. Rutherford, West Hartlepool; J. J. Rutherford, West Hartlepool; F. Essex, Southampton; E. R. Bull, Forest Hill; D. H. Magnus, Morton Park, Wimbledon; H. Holt, Liverpool.

## Exhibitions.

### THE SCOTTISH SALON.

ON Saturday last, February 23, the fourth exhibition of the Scottish National Photographic Salon opened its doors to the public in the Art Gallery of the Paisley Museum. The Salon reflects the progress of the year in Scottish photographic art, and attracts the exhibits of leading Scottish workers at home and abroad. A word as to its arrangements and promoters may not be out of place.

When the idea of this exhibition was first promulgated, the proposal to conduct it on the no-entrance-fees and no-prizes methods was adversely criticised in many quarters, even by those who were in favour of a national exhibition. It was held by many that pot-hunting was too strong amongst "the men who count" to make such a show possible. The advocates of the scheme, however, were dogmatic; they were positive that national pride was still an existent force, and maintained that Scottish workers only wanted the opportunity to prove that in photographic art Scotland was a power to be reckoned with. They confidently prophesied, in the face of the pessimists, that leading workers would loyally patronise an exhibition run on the "all-for-honour" lines. The experiment was tried. The sanguine prophets were right. The leading workers sent of their best. The exhibition was a revelation to most, and the National Salon at one bound took a foremost place amongst exhibitions. The national character of the promoting body—the Scottish Photographic Federation—no doubt contributed in no small degree to the success attained, and it is questionable if it would have been possible for a photographic society—as ordinarily constituted—to have promoted such an exhibition.

Since that first exhibition at Perth in 1904, the quality of the exhibits has steadily advanced; the number of entries are increasing, until this year at Paisley they reach 843, about double the number submitted to the selectors at Perth. These 843 exhibits were entered by about 200 workers. The Board of Selection met, and every frame entered was submitted to their inspection—truly an arduous day's work. The selected pictures number 422, by about 140 exhibitors. There is also a "one-man" show by Mr. C. F. Inston, Liverpool, he having been invited as a representative from England; while Herr M. Masuren, Halle, collected and sent twenty-six pictures representative of the best German and Austrian work (we have already published a list of these exhibitors). The presence of these pictures from England, Germany, and Austria is pursuant of a policy, initiated at the first salon, of inviting work from outside Scotland, different workers being chosen each year, so that native photographers might have an opportunity of contrasting their own work with that of other nations. In this connection it is interesting to note that invitations to exhibit have been given to and accepted by Mr. Percy Lewis, Bristol; Mr. Alex. Keighley, Keighley; Herr Enke, Stuttgart; Mr. F. H. Evans, London.

The Board of Selection this year is: Messrs. J. Craig Anman, Glasgow; Wm. Crooke, Edinburgh; Patrick Downey, R.S.W., Skelmorlie; Alex. Keighley, Keighley; and James Patrick, Edinburgh; and while it is impossible to please everybody, the general opinion is that they have carried out their task well, the result being a collection of works of which promoters and exhibitors may well be proud.

Exhibitors know the various details affecting the Salon arrangements well beforehand. At the annual general meeting of the Federation, held on the opening day of the Salon, it is decided where the following year's Salon will be housed. The Council at an early date, therefore, appoints a Salon Committee and a Board of Selection, and the other details follow as a matter of course.

Portrait photographers in the North are bound to be interested in this year's Salon, as it is particularly strong in portraiture, all the "giants" of the profession being represented. Wm. Crooke is, as usual, forward with a typical collection of his imposing portraiture, one of which, a splendid portrait of an old man, is chosen for reproduction in the catalogue.

John Moffat, Edinburgh, has two strong ecclesiastical portraits, his one of the Dean of Perth (32) being a virile bit of portraiture; while James Auld, Edinburgh, is represented by essays in feminine portraiture. W. R. Kay, Southampton, has a straightforward bit of work in "Portrait of Mr. David Kay" (18); J. B. Johnston, Edinburgh, devotes himself with much success to landscape, as also does his fellow-citizen, James Patrick, who, amongst much good

legitimate work, has an outstanding picture in "Through the Snow-drift" (135). E. Drummond Young, Edinburgh, in two portraits of ladies in mediæval costume (168 and 224), strikes just the right note where he might very easily have wandered into the burlesque. Dan Dunlop, Motherwell, shows idealised portraiture in "Pensive" (49).

C. F. Iaston, in his invited work, shows a variety of portraiture and figure studies, from which much can be learned.

J. M. Whitehead is represented by a splendid collection of his now well-known landscapes. Here we have one of the benefits of specialisation. Mr. Whitehead first took up flower studies, and, having become acknowledged head of that branch of photography, developed a new school of landscape work. It is strictly academic in treatment, but is devoted to the quieter and more peaceful aspects of Nature, treated with a poetic touch that captivates alike impressionist and realist. His work is mostly hung in the centre panel of the north wall, and beside it is a portrait of the artist by G. L. A. Blair, Paisley.

Mr. Blair deserves more than a passing notice. He is a young professional in Threadopolis, who has supported the Salon from the first, turning out good, honest work, mostly landscapes and seascapes of good quality, but this year he has strayed into the world of fancy, and has endeavoured to give a symbolical rendering of the well-known "Lead, Kindly Light" (375). The picture is reproduced in the catalogue, and has already caused much speculation and debate. Rumour has it that the Board of Selection were enthusiastic in their reception of it. The picture is frankly idealistic. On a sandy strip of seashore, dimly lit by a partially clouded moon, a monk carrying a lighted lantern steps boldly forth into the gathering gloom. The attempt is an ambitious one, and while it may not be absolutely successful, it is not by any means a failure, and certainly has made Blair of Paisley the most talked-of man of the 1907 Salon.

A. W. Hill, Shotts, is strongly represented, and several of his "gum-bi" portraits give one pause, and awaken a wonder whether there would not be a market for portraits in that medium amongst the more artistic of our population. J. F. Muir, Glasgow, has the largest number of pictures hung (sixteen), and in a rather uneven collection shows much originality. In this connection we should not omit mention of the Dunlops, of Motherwell, where four members of one family have thirty works accepted.

Dr. Richmond, Paisley, has essayed a fruit study in colours (230). It is by the three-colour gum process (the Doctor being a gum enthusiast), and while it is rather garish, still it gives an indication of the possibilities of the process.

The collection of German and Austrian work forwarded by Herr Masuren has breadth and massiveness for its characteristics. The place of honour is given to "A Quiet Corner" (328), by K. Prokop, a strong massing of light and shade—an old house amongst overhanging trees; sunlight plays all around, and, with all its strength, there is a luminosity in the shadows that is as exceptional as it is pleasing. This worker has other three pictures, his "Austrian Country Dance" (321), depicted in the full blaze of sunshine, has a sense of motion in the whirling figures that one feels to be "just right." Rudolph Dührkoop has six of his quiet and restful "at home" portraits, already well known through the exhibition in the little galleries of the "B.J." and elsewhere in the country. Ernst Müller shows some strong, unhackneyed portraiture, one (332) being reproduced in the catalogue. Dr. Erwin Quedenfeldt shows contrast in attitude in 319 and 340—the scene and figure is the same, yet the one is "Discontented" and the other "In a Good Mood," and both carry out their titles. This exhibitor's strong picture, however, is his "Swan Pond," where most decorative rendition is given of the ripples on the pool. Otto Erhardt has a "big" picture of the immensity of mountain scenery; and toocher landscape (331), original in treatment, and a portrait of a boy, different from the usual thing. Dr. Schrakamp has a picture of broad masses in "Castle of Chillon." Altogether the exhibit is a notable one.

At the entrance, J. Douglas Ritchie, Paisley, held an exhibition of professional work. It comprises a number of large portraits in sepia platinotypes, artistic in treatment, technically excellent, and reflecting every credit on the studio from which they emanate.

Messrs. Kodak, Ltd., Thos. Illingworth and Co., and the Rotary Photographic Co. have also exhibits at the entrance, representative of their various productions.

On Friday evening a private view was held, open to delegates of

the Federated Societies and friends. There was a large attendance, and the pleasure of viewing the pictures was added to and varied by tea, concert, and a lantern lecture by Mr. Henry Coats F.R.S.E., the first President of the Federation. Nothing but praise was heard on every side, and everyone felt that the 1907 Salon had got a prosperous three weeks before it.

#### EDINBURGH PHOTOGRAPHIC SOCIETY.

ON Saturday the annual exhibition of the Edinburgh Photographic Society was held in 38, Castle Street, Edinburgh. The entrance show a slight decrease in numbers, but the quality rivals the best of several years back. Messrs. W. D. McKay, R. Payton Blair, and P. G. Ferras were judges, and in the open section awarded the gold medal to Louis J. Steele, Portsmouth, for his well-known picture, "The Garden of Allah" (10). The treatment is broad and massive, and the whole picture is in harmony. Hon. mention is given to "Through the Snowdrifts" (19), by James Patrick, Edinburgh. In this picture the play of sunlight on the snow and the snowdrift is well portrayed. "Cupid" (26) by R. S. Webster, is a pleasing study of a nude Cupid; and "Geese" (30), by Georg Haranghy de Magyrev Debreczen, Hungary. Other noticeable pictures in this case are colour work by Henry J. Comley, Gloucester—"On the Clear Winding Devon" (42) and "The Night Cometh" (43), by J. M. Whitehead, Alloa; "Twilight" (24), by H. Stewart Wallace; "Child of the Ghetto" (39), by Mrs. Dunlop, Motherwell; "The Beethern Staines" (16), by J. R. Sandilands; A. B. Allan's "Village Carpenter."

In the Members' Class bronze medals are awarded to "After Asti" (172), by J. Trevelyan Sturrock; "Nightfall on the Moor" (178), J. M. Whitehead; "Landing Salmon Nets" (191), J. B. Johnston; "A Portrait" (208), H. Scott Lauder. Hon. mention to "Portrait" (158), Ewen Kennedy; "Figure Study" (166), A. B. Allan; "The 12th. On Birds" (195), W. J. Croall; "After the Day's Work" (197), J. B. Johnston; "Port de Gaud, Bruges" (202), E. L. Brown; "Towards the West" (216), J. B. Johnston. Other noticeable pictures in this class are: "Through Many a Storm" (200), W. J. Crear; "Love Lightens Labour" (192), James Patrick; "When the Tide is Out" (193), Geo. Cleland; "A November Morning" (199), James Burns.

#### BIRMINGHAM PHOTOGRAPHIC SOCIETY.

THE twenty-second annual exhibition of the Birmingham Photographic Society was opened, in the beautiful galleries of the Royal Society of Artists, on Friday evening, February 22, by a reception and private view, given by Mr. Thomas Taylor, the president. Mr. Taylor has well earned the highest honour the society can bestow for he has been one of its most faithful friends from the day the society was founded, nearly twenty-five years ago, and he is one of the two original members left.

It is difficult to compare one exhibition with another, and last year was so startling in its excellence that it was not to be expected that this year's would rival it. Although one of the judges expressed the opinion that this year's exhibition was even better than last year, we think that the average individual will scarcely agree with him. But everyone must admit that it is a remarkably good one. The local work is quite equal to anything in former years, but the extraordinary display of foreign photographs of last year is not attained this time.

The judges—Messrs. J. R. Bland, Alexander Keigley, and J. T. Wainwright, R.W.S.—have evidently been greatly impressed by the quality of the work exhibited, for they have been extremely lavish, not to say prodigal, with their awards, having given no fewer than five silver, fourteen bronze, medals, and twenty-three honourable mentions in the pictorial sections.

In the members' section Mr. W. A. Clark takes the silver medal for his "Nocturne, Gloucester." Apparently an exposure, made by the last gleams of day and a lighted street lamp. It is very successful, but we think the composition would have been improved by reducing the patch of light on the right side and by showing a gleam of light inside the dark passage in the centre, which would show that there is a passage through the arch; at present the arch appears closed by a black door.

No. 26, "Crypt, Gloucester," and No. 40, "A Corner of the Cloister," are also by Mr. Clark. Both received bronze medals. The

former is a good rendering of the wonderful Norman under-church, with a ray of sunshine streaming across, but, like most photographs of the place, fails to render the intense gloom of the original. The second is also at Gloucester, showing a corner of the cloister near the famous lavatory. No. 75, "Ruth," by Mrs. Dora Leckie, is a charming head by a new comer, but the effect and concentration of interest would have gained enormously if the upper part of the print, the top of the head, and the background, had been darker; there is an unpleasant fading away at the top, which damages the general effect and rather suggests a fogged plate. Admirers of Mrs. G. A. Barton's work will be disappointed by her photographs shown here. No. 3, "Florence and Paul Dombey," is certainly a breaking of new ground, but it can be scarcely called a conspicuous success. The figure of Florence does not recall the charming girl of the book, either in grace or beauty; and of Paul we can see but little, on account of the size and whiteness of his necktie, which is the most prominent object in the composition, while the bouquet he carries attracts attention at once by the careless way in which the density of it has been reduced by rubbing. No. 7, "Madame Pharnion," a profile of an old lady, is altogether pleasing. No. 9, "Madame de Goade," is also excellent, and would be still better if the high lights on the face were not so very sparkling. Mrs. Arbuthnot contributes several dainty and pleasant renderings of Italian scenes. We hope this lady will continue to cling to the sketchy, dainty style she succeeds with so well. It is so pleasant in these days of murkiness and gloom. Miss Lillie Bruce receives a bronze medal for No. 71, "Steam," a good study of steamers and smoke; and Miss Ethel Barrows a like award for a good head study.

No. 43, "Playmates," by Mrs. Wootton, is a pretty picture of a little girl on some garret stairs nursing a kitten. It will be seen that the lady members of the society quite hold their former prominent position.

Mr. E. D. Taylor scarcely fulfils his promise of last year. His "Bit of Old Worcestershire" is good, but wants more positive concentration of light and dark, and some more prominent point of interest. Mr. Lewis Lloyd, the indefatigable hon. sec., has received two honourable mentions. No. 64, "The Iron Horse," is a picturesque impression of a huge modern railway engine, nearly hidden by escaping steam.

No. 54, "A Bit of Old Conway," by A. G. Asman, would be greatly improved if the distant buildings receded. One effect often seen in "gum" prints is want of recession of the distance; it is failing that one would not expect to see in prints by a process which is said to give such great "control"; but there are many fine landscapes in the galleries, which show that this defect is not inherent in the process.

No. 69, "The Avon," by Reg. Gilbert, gives a good idea of that beautiful river, with its rushes and willows, and a fine sky. It is a picture to live with. In No. 77, "Flora MacLeod," one recognises some of Mrs. Barton's favourite models in her well-known style, but the contrasts of light and dark are very strong. In No. 79A, "Girl With Hat," by Miss Ethyl Barrows, the shadows on the face are unnaturally strong. If photographers would only carefully study the deepest shadows on a strongly lighted face they would see that they are never as dark as the shadows in the hair or clothes, yet we constantly see them reproduced in photographs as dark as the blackest shadow in dark drapery.

In the open section there is some fine work. No. 84, "In Norway," by J. Dudley Johnstone, is a good Corot-esque landscape in gum, but the blue sky seems out of place in a monochrome. No. 87, "A Sunlit Street, Berne," there is the same curious blue sky and pavement, which very much detracts from a beautiful effect of sunlight in a busy street. It is pleasant to see the original "The White Bridge," No. 90, by the same, after seeing it so often reproduced. No. 88, "Storm Clouds," by George Haranghy, is a very powerful and effective print in dark blue.

Nos. 81 and 93, by Henry J. Cowley, are wonderfully true renderings of still life in colours. No. 93, "Oranges and Nuts," takes an honest, and the fidelity of colour is remarkable, especially in the oranges; but the piece of tissue paper on the left seems to us a little too blue in colour. On the whole, we prefer No. 81. But we cannot help feeling that these brilliant reproductions of colour, wonderful as they are, give a too vivid effect. There is always

a great deal of grey in nature, especially in half shadows, but here all seems brilliant colour. Is it caused by the negatives being too brilliant and lacking in delicate half-tone? We do not see the same defect when artists' drawings are reproduced. Think of those marvellous reproductions of Arthur Rackham's illustrations to "Rip Van Winkle."

Charles F. Stuart sends several very fine landscapes in gum—No. 98, "Summer's Noontide," No. 106, "Evening's Lengthening Shadows"—and in "Auld Reekie" we have one of the finest things in the exhibition, a grand effect of smoke and steam in the railway cutting below Edinburgh Castle. It seems strange, when awards have been scattered so liberally, Mr. Stuart gets nothing. No. 134, "Chill October," is also excellent, but unfortunately the title at once recalls one of Millais's great landscapes, and the photograph has to take a back seat. No. 162, "Loch Katrine," is another of Mr. Stuart's grand landscapes, but it is sadly marred by a dark line along the top of the far distant mountains. S. G. Kimber sends a number of very beautiful architectural studies, the finest being "A Cathedral Passage"—No. 189, a superb photograph of the Stype or Abbot's Cloister at Gloucester. One wonders why it did not get an award. Another nearly as good is No. 113, "A Relic of the Past," also a Gloucester view, showing the old cope chest. No. 100, "Steps to the Chapter House Wells," is perhaps the best of this most beautiful, but impossible, subject for photography we remember to have seen, not forgetting F. H. Evans' "Sea of Steps." No. 170, "Child of the Ghetto," by Mrs. Dunlop, is a good, broad, natural portrait, quite refreshing after the artificiality of some attempts around it. Mrs. Girdlestone has made several strong efforts to get away from conventionality in No. 129, "A Dream of Beauty," and No. 135, "L'Introse." They are scarcely successful. It is rather difficult to see what they are all about, and in No. 129 there is a strong streak of shadow athwart the forehead that is unpleasant and unnatural. Dr. Thurstan Holland sends only one print a very fine "ozo-bromide" of one of those groups of mountains in snow, for which he is famous. Edward B. Pain, in No. 116, "The Waters of Lethe," has a really fine effect of steam and smoke from blast furnaces over a canal; but why did he put the sketch of the demon, with pitchfork all complete, on the flat of the frame? It has nothing to do with the subject and only irritates by detracting attention from the picture. J. C. Batkin secures a beautiful suggestion of fresh air and open space in No. 119, "Fresh Breeze and a Winnowing Sand," and in No. 132, "Bright Visions in a Dreary Waste." T. H. Cox's "Student of English," gives a pretty pleasant study of a little Dutch girl at her book. No. 127, "A Volendam Canal," by James Gale, is capital, composed, with a figure of a Dutch girl in the foreground; but the general effect seems to want a little more vigour and contrast. C. J. Cruwys Richards has left for the present his experiments in coloured gum, and his three studies in an Irish cabin, printed in black carbon, are excellent—No. 130, "Anxiety," No. 136, "Portrait," and No. 293, "In an Irish Cabin"—but, unfortunately for the first one, we cannot help thinking of Frank Bramley's "Hopeless Dawn," and the photograph, good as it is, suffers from recollections of the picture. No. 163, "The Dairymaid," a Swiss scene apparently, is in gum; but it is not as good as we have a right to expect from Mr. Richards; the colour is unpleasant, a curious yellowish brown, and some of the shadows, which we should expect to see the darkest, are very weak; the print is unequal. It is rather like the curate's egg—some parts are excellent, but others are disappointing.

Herbert E. Wroop exhibits several dainty platinotypes, apparently vignetted by the glycerine method; they are very fresh and pleasant.

Nos. 140 and 155 are delicate photographs of the semi-nude bronze figures, carrying electric lights, in the square at Leeds, and very charmingly rendered. No. 148, "Winter," by J. E. Sykes, shows a sparkling, glittering effect of sunshine on snow, very fresh and true. George Haranghy, No. 102, "The Mill," is another snow scene of a different type, very strong and broad. No. 181, "A Play of Sunlight," by J. W. Johnson, shows a vista through panelled rooms with a well-caught effect of sunshine on the floors and walls; but it is sad to see that the beautiful rooms are falling fast into decay.

G. C. Dudley's "Pathless Snow," No. 188, is just as strong as J. E. Sykes' "Winter," is bright and sparkling, but just as true in its own way; it is a fine print. J. M. Whitehead sends several landscapes of the poetical kind we expect from him, and by far

the best is "The Silent Moor," a broad expanse of heather-clad undulations, with a sunset sky. It well deserves the bronze medal it receives. Arthur Marshall's "Venetian Pearl," we all know and admire. Dr. Ledenig, of Graz, has several fine things. No. 209, "Birch Trees," we consider the finest photograph in the exhibition. It suggests misty moonlight through a group of leafless trees. It is at once a strong, poetical, and pictorial print. It is to us just perfect, except for the glaring light coloured signature just where it ought not to be. No. 258, bearing the same title, is quite a different subject. Here we have two curiously shaped trees, blown about. The suggestion of driving wind in the trees and the clouds is grand, but the top of the taller tree, near the frame, is ugly and solid, and we think it might be trimmed off with advantage. We are glad that the former has received a silver medal.

Miss Annie E. Bridgman sends six attempts to produce the weird-poetic by photography. We must confess that, to us, they are quite failures; they are weird, but, oh! so ugly. No. 244, "The Soul of the Blasted Pine," shows a very material nude model, doing gymnastics on a fallen tree. It is of the earth earthy, and the others are much of the same kind.

No. 307, "La Petite Hollandaise," by P. Dubreuil, is an example of faking, naked and unashamed, but all the high lights are intensified by some means which suggests that the surface of the print has been scraped down to the white paper. If this work is on the negative it seems doubly indefensible; in the first place, because it is apparent; and in the second, because it imitates another method of work. Faking is only pardonable when it is not found out. No. 309, "Mother and Child," by F. H. Pratt, well deserves its bronze medal. It is a beautiful unconventional portrait group.

It is quite impossible to notice all the good things in the galleries, but we may ask why M. Demachy's, and many other beautiful prints, are hung in a dark passage where they can hardly be seen?

#### FORTHCOMING EXHIBITIONS.

1907.

February 22 to March 4: Norwich and District Photographic Society.—Sec., J. T. Tanner, The Lodge, Norwich.

February 23 to March 2: Birmingham Photographic Society. Entries close February 12.—Sec., Lewis Lloyd, Norwich Union Chambers, Birmingham.

February 23 to March 9: Edinburgh Photographic Society. Entries close February 9.—Sec., H. Stewart Wallace, W.S., 77, George Street, Edinburgh.

February 23 to March 16: Scottish National Salon. Entries close January 31.—Sec., Robert Milne, Linnvale, Potterhill, Paisley.

February 25 to 28: Worthing Camera Club. Entries close February 16.—Sec., E. F. H. Crouch, 11, South Street, Worthing.

February 26 to March 2: Norwich and District Photographic Society. Entries close February 12.—Sec., J. T. Tanner, The Lodge, Bowthorpe Road, Norwich.

February 27 to March 2: Nottingham Camera Club. Entries close February 14.—G. R. Cranch, St. Jude's Avenue, Nottingham.

February 28 to March 7: Queen's Park Amateur Photographic Society. Entries close February 14.—Sec., J. Moir, 644, Cathcart Road, Glasgow.

March 2 to 9: South London Photographic Society.—Sec., W. L. White, Bank House, Ladywell, London.

March 2 to 24: Marseilles Photographic Society.—Sec., M. Cullet, Rue St. Savournin, 38, Marseilles.

March 6 to 8: Aldershot and District Camera Club. Entries close March 2.—Sec., D. Morrison, Kilry, York Crescent, Aldershot.

March 6 to 9: Wearside Camera Club. Entries close February 20.—Octavius C. Wilmot, 297, High Street West, Sunderland.

March 6 to 9: Bolton Amateur Photographic Society. Entries close February 16.—Sec., Gilbert Holt, 187, Deane Church Lane, Bolton.

March 7 to 16: Leicester and Leicestershire Photographic Society. Entries close February 16.—Sec., Lewis Ough, "Fernleigh," St. James' Road, Leicester.

March 12 to 13.—G.E.R. Mechanics' Institute, Stratford (photographic section). Entries close March 2. Sec., A. Woolford, 16, Grove Green Road, Leytonstone, N.E.

March 14 to 16: Coventry Photographic Club. Entries close March 9.—Sec., T. J. Mercer, 6, Cope Street, Coventry.

March 22 to April 13: Northern Photographic Exhibition. Entries close March 8.—Sec., C. F. Inston, 25, South John Street, Liverpool.

March 23 to April 2.—Glasgow Southern Photographic Association. Entries close March 16.—Sec., Charles Young, 217, Colinton Road, Partick, Glasgow.

April 10 to 13: Ilkeston Arts Club, Photographic Section. Entries close March 27.—Sec., A. Smith, 11, Graham Street, Ilkeston.

April 17 to 19: Belfast Y.M.C.A.—Sec., J. W. Bushey, Y.M.C.A. Camera Club, Belfast.

April 25 to 27: Wallasey Amateur Photographic Society. Entries close April 10.—Sec., W. Hayes, 110, Brighton Street, Seacombe.

April 29 to May 14: Photographic Society of Ireland. Entries close April 22.—Sec., R. Benson, 35, Molesworth Street, Dublin.

May 6 to 10: Chemists' Trades.—Sec., A. Norman Flack, "British and Colonial Druggist" Offices, 44, Bishopsgate Street Without, London, E.C.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications were made for patents between February 11 to 16:—

PHOTOGRAPHY AND BURGLARY.—No. 3,345. Automatic service for photographing housebreakers whilst manipulating on the door lock. Hubert Wessling, 53, Graben Strasse, Essen, Ruhr, Germany.

CAMERAS.—No. 3,607. Improvements relating to photographic cameras. Henry Major, 24, Carlholme Road, Forest Hill, London.

ELECTRO-CHEMICAL PHOTO-PRINTING.—No. 3,714. Improvements relating to cameras for producing photographs by electro-chemical or the like means. Frederick Otto Trautmann, 37, Park Road, Loughborough.

FOCAL-PLANE SHUTTERS.—No. 3,810. Improvements in connection with photographic exposure shutters, known as self-closing focal plane shutters. John Stuart and Alfred Woods, 47, Lincoln Inn Fields, London, W.C.

DARK SLIDES.—No. 3,841. New or improved combined magazine and dark slide for photographic plates, and the like. Walter William Niblett, 88, Chancery Lane, London, E.C.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

OPTICAL PROJECTION.—No. 15,729, 1906. The invention relates to a system whereby transparencies may be projected at any angle and is particularly applicable for advertising purposes. It consists in principle in inclining the optical axis in relation to a surface which receives the projected image, and in placing the projection apparatus, at a corresponding inclination (determined by convenience) a specially-prepared slide.

Let A B be the position on the ground upon which the image is to be projected, and O the point where the objective of the projection apparatus is to be placed. In order to determine the position which the slide should occupy in relation to the objective, it is first necessary to determine the optical axis, which may be represented by the line adjoining the point O with the centre M of the line A. B. The optical axis F F' and the line of the objective being known, it will be easy to determine the known processes the positions *a b* which those points of the slide should occupy that are to be projected at A and B. To test the line *a b* in size and position it is sufficient to determine a single one of its points; for example, the point *m* of this line which is found in the optical axis. The point *m* having been once determined, in order to obtain the position *a b* of the slide it is sufficient to join this point *m* to the point C where the line A B intersects the median plane O C of the lens. The extreme points *a b* of the slide will then be found at the intersection

the line  $mC$  with the lines  $AO$ ,  $BO$ , and similarly for all points of the image.

It is to be observed that the image  $AB$  is not geometrically similar to the slide  $ab$ , the point  $m$  not being at the middle of  $ab$ , and that the image  $AB$  will not conform to a predetermined subject unless it has been projected by the aid of a slide  $ab$  representing the subject distorted correspondingly. Thus, to obtain upon the ground an image similar to a given subject, it is

necessary to employ a special slide carrying a distorted image which can be determined either by tracing it point-by-point, or preferably in practice by photography. In the latter case the sensitive plate, the objective and the subject to be photographed would occupy relative angular positions which may be conveniently determined by a process analogous to that above specified and represented in the annexed figure. James Tiburce Felix Conti, 8, Quai d'Orleans, Paris.

**New Trade Names.**

- No. 289,359. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. A. Drake Roberts and Co., Ltd., 100, Carpenters Row, Stratford, Essex, Manufacturing Chemists. January 8, 1907.
- STEMPERETTE.—No. 289,506. Chemical substances used in manufactures, photography, philosophical research, and anti-corrosives. W. H. Holmes and Sons, Stepney Paint Works, Turner Street, Portland Road, Newcastle-on-Tyne, Paint and Colour Makers. January 14, 1907.
- IPIDO.—No. 286,122. Photographic apparatus in Class 8. Fabrik Photographischer Apparate auf Aktien vormals R. Hüttig und Sohn, 76, Schandauer Strasse, Dresden, Germany, Photographic Manufacturers. September 22, 1906.
- XIO.—No. 289,081. Stereoscopes and parts of stereoscopes included in Class 8. Leon Pigeon, 3, Millotet, Dijon, France, Manufacturer. December 22, 1906.

**FEATS OF THE CINEMATOGRAPH.**—The Palace Theatre scored two distinct bioscope records last Saturday afternoon. The wreck of the "Berlin" was shown in a series of episodes vividly depicting the disaster. The rescuers are seen embarking on their perilous undertaking, and later, the ill-fated "Berlin" with the waves breaking over her. Their Majesties the King and Queen opening the South African Products Exhibition was also shown on the bioscope on Sunday within three hours of its occurrence and a unique feature that of the King in the act of knighting Captain Bam.

**SIR BENJAMIN STONE** has just returned after a long holiday with the camera in Egypt. The Unionist member for East Birmingham, it appears, paid particular attention to the beautiful ruins of Kom Ombo, and also to the recently excavated tombs of the Queens near the plains of Thebes, but undoubtedly the most interesting of the photographs he has secured are in connection with the tomb of Amen Teie. Sir Benjamin had the good fortune to be present when Messrs. T. Davies and Curdely opened the tomb containing so many wonderful relics, and of these he has made numerous photographs.

**HALIFAX CAMERA CLUB.**—Mr. Lionel Dickinson, secretary for the last seven and a half years, has retired from the position, his successor being Mr. Harry Crossley, 29, Beech Street, Pellon Lane, Halifax, to whom it is requested all communications on club matters could be addressed.

**Analecta.**

*Extracts from our English weekly and monthly contemporaries.*

**A Preservative of Soda Sulphite Solution.**

The addition of glycerine to sulphite solution (writes "F. G. P.," in "The Amateur Photographer," of February 26) acts as a preserving agent, while it in no way interferes with the chemical action of the developer. The following is the formula:—

Sodium sulphite .....	5 ozs.
Glycerine .....	3½ drms.
Water .....	1 pint.

This makes a good stock solution, which may be diluted as desired. It will keep for six or eight months easily, without deteriorating to any practical extent. Other substances, such as mannitol, have the same effect, but are less readily obtainable.

**Firelight Effects by Daylight.**

Writing in "Photography," of February 26, Mr. Henry Essenhighe Corke describes a method of securing portraits and figure studies shown under a lighting like that from a domestic fireplace. He says:—"In the case of those taken in the studio, the sitter was posed on a raised platform, so as to be on a level with the bottom of the window, in this case of ground glass, and about two feet from the floor. The sitter should be as near the source of light as possible, so that the lighting may be rather concentrated. All the dark blinds are then drawn, leaving only a patch open about two feet square,

just in front of the sitter, where the fire is supposed to be. A fender and hearthrug are then placed in front of the light on the floor. In some cases it may be found convenient to place a mirror in the "fireplace," so as to give an extra amount of reflected light upwards to the face of the sitter. A small strip of white paper may be placed inside the fender to look like the white hearth.

"It is desirable to use a dark background, composed of dark curtains; these should not be allowed to hang in folds, but should be stretched tightly, or awkward streaks of high light will possibly show on the folds.

"Exactly the same effect can be obtained in the same way in an ordinary room, and at an ordinary window."

[Some time ago Mr. Corke sent us a photograph of his studio showing the arrangement for obtaining the firelight effect. The illustration is so explanatory of the above description that we may reproduce it here.—Eds. "B.J."]

**Ozobrome Lantern Slides.**

The Ozobrome tissue (writes Mr. W. Findlay, in the "Photographic News," of February 22) is sensitised, as directed by the makers (immersed for one minute in the special solution), and squeezed into contact with the print from which the lantern slide is to be made. The print should be first well soaked in water, and,

after squeegeeing, left for an hour in contact under slight pressure between sheets of damp blotting-paper. This is an important point. If it is omitted, the further transfer necessary is rendered difficult.

At the expiration of the hour, the print with the adhering plaster is immersed in cold water, and under it they are separated. The former is now non-existent, but is re-developed later, and is generally none the worse. The tissue is immediately squeegeed on to a cover-glass on which there is no substratum. This is placed between dry blotting-paper and left for twenty minutes, to allow for a good adhesion.

The embryo side is then immersed in a dish of lukewarm water. A sufficient time is allowed for the backing paper to free itself from the pigment, and then this is peeled off. It comes away readily, and there is no image on the face of the paper such as one expects to find in the case of a correctly exposed carbon print.

Development is allowed to proceed, and the unaffected pigment is rather slow in coming away. No more warm water need be added, however, and in about five minutes' time a good slide—an exact replica of the print—is obtained.

### The Arithmetic of Dry Mounting.

The editors of "The Photographic Monthly" (née "The Photogram"), with whom systematisation amounts to a religion, gives the following table of temperatures for the guidance of dry-mounters:

	Deg. Fahr.	Deg. Centi.
Carbon and "gum" prints .....	140-150	60-65
Gelatino-chlorides, lightly alumed .....	160	70
" " strongly alumed .....	165-175	75-80
Colloidio-chlorides .....	185	85
Bromide .....	185-195	85-90
Albumen .....	195	90
Platinums, plain-salted silver, "Mattos," and other prints with matt faces and no gelatine .....	195-205	90-95

These temperatures are for five seconds' pressure, but slightly lower temperatures and a longer dwell are recommended. Within very wide limits the variations of temperature will do no real harm. If too low, neither the print nor the mount will stick to the adhesive sheet; if much too high, the adhesive sheet will generally stick to the print and come away from the mount.

With very thick papers the temperature may be increased a little and the time be lengthened to fifteen or twenty seconds.

Unmounting is quite easy. Heat a metal plate to 250 deg. or 300 deg. Fahr. (120 deg.—150 deg. C.). Lay the mount upon it, and with a piece of flannel press a corner of the print, until it is loose. Raise this corner, then press an adjacent part until it, too, comes loose, and very quickly the whole print can be stripped without injury.

## New Books.

"Three Vagabonds in Friesland with a Yacht and a Camera." By H. F. Tomalin. 250 pp. and xxvi. 8 by 6 inches. London: Simpkin, Marshall, Hamilton, Kent, and Co., Ltd. 7s. 6d.

The yacht was hired, the camera was Mr. Arthur Marshall's. Hence the interest to us and to all photographers of this narrative of the wanderings of a photographer and two friends on the "meers" and canals of Northern Holland. The book is one answer to the eternal question: "Where to go this year?" Try this quaint corner of Holland, say the authors, and adduce in support of their advice the account of a month's journeyings which admirably reproduces the restful easy-going life of a part of Holland which is inconceivably remote from the beaten track of the tourists, yet only fifteen hours from Liverpool Street.

Mr. Marshall's photographs—made with a 5 by 4 reflex camera, as he tells us—are quite as necessary a part of the narrative as the text. Without pretensions to be more than "snap-shots" taken with some care, they are many of them highly pictorial, and the quaint costumes of the Dutch men, women, and children are the subject of many most pleasing compositions. The cost of this delightful holiday, we read, worked out at £1 a day for each of the three "vagabonds," and we have no doubt that the "architect," "printer," and "scribe," as the trio are individually labelled by

the last-named, had a glorious time. The narration of how their holiday was spent in doing nothing in particular has few dull places in it. Indeed, our only quarrel with the author is that he seems to be constantly trying to reproduce the humour of Mr. Jerome K. Jerome's "Three Men in a Boat."

Mr. Marshall contributes an appendix containing an interesting account of his photographic equipment and procedure *en route*.

"Exécution des Fonds d'Atelier." By H. Fines. Forty pages, 8 by 5. Paris: Chas. Mendel. 60 centimes.

M. Fines, the author of this little work, is a painter of backgrounds for professional photographers in Paris, and was at one time a scene-painter for the Opera. He instructs the reader in the making of a background from beginning to end by the distemper and flatted oil methods. Commencing with the construction of the framework, he deals with sizing and the application of colour to plain and clouded grounds, interior, and landscape subjects, and to ground cloths. Finally, he gives a series of hints on the repair of backgrounds. The volume is evidently the work of one who is thoroughly acquainted with his subject.

## New Materials.

Barnet "Oyster-shell" Gaslight Paper. Made by Elliott and Sons, Ltd., Barnet, Herts.

From the jungle to oyster beds is a far cry, but the breach is traversed by Messrs. Elliott in their search for a name for their new introduction, the character of which is far removed from that of the "Tiger Tongue" paper. "Oyster-shell" happily emphasises the peculiar coolness and delicacy of the results with the new paper, results which evade exact description, yet are assets of considerable value both to the amateur and professional photographer. The latter particularly has reason to take notice of the new paper, for it is still another instance of the continual improvement of bromide as a printing process which can be used for portraits of the highest class. Its pure black, "colour" of image, clear high-lights, and subtle matt surface produce altogether an effect which a photographer can apply to his own work with great distinction, especially if he study the particular fitness of mounting boards for the reception of "Oyster-shell" prints. Messrs. Elliott have issued small window-bills which supply an admirable object lesson in this respect. The imitation grey canvas surface, with just a tinge of green in it, makes a perfect surround for the soft prints on the new paper.

Leto Pigment Paper. Made by the Leto Photo-Materials Co. (1905) Ltd., Rangoon Street, London, E.C.

In this material we have still another addition to the now quite considerable number of papers for the production direct of a pigment image—that is to say, without transfer to a temporary or final support, as in the carbon process proper. The forerunner of all these papers may be said to be the well-known "Artigue," to which, indeed, the paper now under consideration, bears a very strong resemblance as regards the results procurable with it.

The paper is sensitised in a rather special way, otherwise all the manipulations are those familiar to users of direct pigment papers. The sensitising bath is:—

Ammonium bichromate.....	450 grs., 50 gms.
Sodium carbonate (cryst.).....	90 grs., 10 gms.
Water up to.....	20 oz., 1,000 c.c.s.

This is diluted immediately before use with twice its volume of methylated spirit and the diluted solution discarded after use. The sensitiser is applied by brushing, placing the print on a board tilted so that any excess of liquid runs off at once from the print. In this way the print absorbs a less amount of sensitiser than it would by floating or immersion, and it dries in about 10 or 15 minutes. It should be used within forty-eight hours, or it becomes stale and flat in working.

As regards the further treatment there is no point of difference from that adopted in previous papers of this class. The prints are developed in hot water, which is poured upon them from a jug or the tap, or they may be very lightly treated with a soft brush (with which also any amount of "control" may be introduced), or they may be developed in a broth of hot water and fine wood meal. In all cases, the results in our experience show a fine range of gradation.

and pleasing texture. The paper is sold in shilling packets of twenty quarter-plate, or nine half-plate, pieces, and is also obtainable in larger sizes up to 15 x 12. Accessories in the shape of sensitiser, tintometers, and developing sprays are also supplied by the Leto company.

**"ELTICO" ART MOUNTING BOARDS.**—Messrs. L. Trapp and Co., and 9, Chiswell Street, London, E.C., send us a sample booklet of series of fine art boards and papers which they are issuing specially for mounts and folders. In both colour and surface the series offer variety which is an improvement on any we have seen. The colours are none of them pronounced. They include browns, greys, and tints of very agreeable and unobtrusive shades, and in the case of the boards, possess a linen grain very closely resembling some of the mounting boards used by Herr Dührkoop for the photographs shown to our offices a year ago. Messrs. Trapp send the booklet to any professional photographer for sixpence, and we imagine that every one aiming at distinction of style will wish to avail himself of the offer.

**THE SCHROEDER LIGHT.**—Mr. Jonathan Fallowfield, 146, Charing Cross Road, advises us that he has had a consignment of the Schroeder lamps sent over, and will be pleased to show those interested the working of the lamp in London. From practical trials and from letters received from professionals who are at present using this apparatus, it is recommended with every confidence. The price is £6 6s., and includes carrying case.

**OIL PRINTING.**—Messrs. John J. Griffin and Sons, Ltd., inform us that they have made arrangements to supply the materials for the printing process with which Mr. Rawlins's name, and lately those of M. Demachy and Puyo, have been associated. They will also give demonstrations of the process every Tuesday afternoon at 3.30 at their house in Kingsway. A list of prices of oil-printing requisites will be sent by Messrs. Griffin on application.

**"TABLOID" CHEMICALS.**—To enable photographers to make a practical test of "Tabloid" photographic chemicals, and familiarise themselves with the convenience and reliability of these products, Burroughs, Wellcome, and Co. are now issuing specimen sets of "Tabloid" photographic chemicals to retail at 6d. and 1s. The former contains metol-hydroquinone developer, potass bromide, and sulphide; the latter, in addition, pyro developer, persulphate, and gold-toning preparations.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### FRIDAY, MARCH 1.

Hamstead Scientific Society. "Sponges: Their Life-history and Development."  
M. Yeatman Woolf, F.R.S.  
London Photographic Club. "Members' Prints."  
London Photographic Society. "Art and Photography." C. O. Murray.  
London Photographic Society. "The Life of a Flower." A. McKinnon.  
London Art Club. "Federation Portfolio."

#### SATURDAY, MARCH 2.

London Photographic Society. "Picturesque Japan." Illustrated. J. Duncan Millar. Art Union Drawing.

#### MONDAY, MARCH 4.

London Polytechnic Photographic Society. "Enlarged Negatives on 'Rotograph' Negative Paper."  
London Photographic Society. "Leading Principles in Velox Manipulation."  
London Photographic Society. Monthly Lantern night.  
London Camera Club. "Visp to Zermatt." Illustrated.—Part I. W. R. Kay.  
London Park Photographic Society. 1906 Outing. Lantern Slide Competition.  
London Camera Club. "Suggestions on Pictorial Photography." Lantern Lecture.  
A. A. Bellingham.  
London and Forest Hill Photographic Society. "Principles of Composition."  
W. E. Tindall.  
London's Heath and Moseley Photographic Society. "Cathedral Photography."  
W. A. Clark.

#### TUESDAY, MARCH 5.

London Photographic Society of Great Britain. "Wet Collodion, Negative and Positive." By the Autotype Company.  
London Camera Club. "Postcard Photography on 'Rotox' and 'Rotograph' Card."  
London City Camera Club. Carlisle. "Theory and Practice of Self-Toning Papers."  
London John J. Griffin & Sons.  
London Crow Naturalists' Field Club. "Theory and Practice of Self-Toning Papers."  
London John J. Griffin & Sons.  
London Glasgow Southern Photographic Association. "Sports and Pastimes with the Goetz-Anschutz Folding Camera."  
London Otherham Photographic Society. "Intensification and Reduction."

Sheffield Photographic Society. "Some Points in Making Lantern Slides." G. D. Harrison.  
Stafford Photographic Society. "Holland and the Rhine." H. Cliff and H. Hey.  
Redhill and District Camera Club. "Colour Photography." E. E. and C. Robinson.  
Handsworth Photographic Society. Council Meeting.  
Worthing Camera Club. "Theory and Practice of Self-Toning Papers." Demonstrated. John Griffin & Sons.  
Darlington Camera Club. "Japine Platinotype." F. Airey.  
Hackney Photographic Society. Annual Meeting.  
Sheffield Photographic Society. "Some Points in Making Lantern Slides." Demonstrated. G. D. Harrison.

#### WEDNESDAY, MARCH 6.

Derwent Valley Photographic Society. "Enlarging Simplified." John Griffin and Sons.  
Friends School Photographic Society (Sheffield). "Contact Printing on the 'Rotograph' Slow Paper."  
Bideford Camera Club. "What can be done with a Hand Camera." C. P. Goerz.  
Hamstead Scientific Society. "Printing Processes." Edward Seymour.  
Bristol Camera Club. Prints Criticism.  
Bristol Photographic Club. "Technical Negative Making." R. W. Coates.  
Edinburgh Photographic Society. "Some Experiences of a Professional Photographer." T. Drummond Shiels. "Some Experiences of an Amateur Photographer." James Burns.  
North Middlesex Photographic Society. Lantern Slide and Print Competitions.  
Borough Polytechnic Photographic Society. "All at Sea with a Hand Camera." E. J. Mortimer, F.R.P.S.  
Woodford Photographic Society. "An Idyllic Minster of the West Country." E. W. Harvey Piper.

#### THURSDAY, MARCH 7.

Darwen Photographic Society. "Stereoscopic Photography." C. P. Goerz.  
Tynemouth Photographic Society. Telephotography. C. P. Goerz.  
Ashbourne (Derby) Photographic Society. "Enlarging on 'Rotograph' Bromide Paper, including a Chat on Toning Bromide."  
Chelsea and District Photographic Society. Lantern Evening.  
Handsworth Photographic Society. Lantern Evening—Members' Slides.  
Leicester and Leicestershire Photographic Society. Exhibition.  
Rugby Photographic Society. "Novelties in Photographic Apparatus and Materials."  
Tunbridge Wells Amateur Photographic Association. "A Visit to English Cathedrals." H. W. Bennett.  
London and Provincial Photographic Association. "Selection of Apparatus." Ernest Human.  
Richmond Camera Club. "Platinochrom." O. Sichel & Co.  
L.C.C. School of Photo-Engraving. "Some Notes of English Caricature." W. B. Dalton.  
Liverpool Amateur Photographic Association. "Norman and pre-Norman Stonework." Frank O. Groswell.  
Hull Photographic Society. "Features of Lenses." F. W. Doughty.  
North London Photographic Society. "Platinochrom Printing." O. Sichel and Co.  
Blenheim Club. "Picturesque India." E. R. Ashton.  
Blyth and District Camera Club. "Amateur Photographer Prize Lantern Slides."

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held February 26, Mr. E. J. Wall in the chair. Mr. E. C. Middleton, of Birmingham, read a paper on "Half-tone Negatives," and a Suggestion for Securing Uniformity in the Same." Mr. Middleton discussed the current method of employing more than one stop in making negatives with the half-tone screen. The results were never so good as when one stop only was used, and he regarded two or three stops as a means of helping the inefficient operator. The theory of the half-tone process had never been worked out thoroughly. Experiments had been made by Dr. Eder and others under certain fixed conditions, but when the conditions were changed the theory which had been evolved broke down.

The method which he had worked out whereby he could place the making of negatives with absolute uniformity in the hands of an assistant knowing nothing of the work, was based on the assumption that equal quantities of light would produce equal results in half-tone negative making. He kept the screen at a fixed distance from the plate, about one-eighth of an inch in his own case, and he adjusted the diameter of the diaphragm to the extension of the camera so that the former was always the same proportion, say, one thirty-fifth, of the latter. In this way he secured a regularity which was a great saving of labour in the printing and etching rooms.

Mr. A. J. Newton said he should like to see the results of the method on a graded scale of tints. It was his experience, and the experience of half-tone operators in general, that the most perfect results were obtained by the use of two stops, and, contrary to the contention of the lecturer, the middle tones of a subject were better rendered in this way than with one stop. He did not employ the stops with elongated corners recommended by the lecturer, for he found that every effect and perfection of result could be obtained with round stops when working from a variety of originals.

Mr. Fogwell said he preferred to employ one stop only. He could not endorse the lecturer's statement that a negative should have the dots free from all halo. It was an advantage to have some halo, or

"scum," on the dots of the middle tones. It was a great mistake, he said, to aim at the same class of negative when using dry plates for half-tone work as when using collodion.

Mr. Middleton, in reply, said that his work had been done exclusively with collodion.

Mr. John Sterry then read a paper on "The Action of Oxidisers on the Development of the Latent Image." His experiments had completely confirmed the statement of the late M. Leon Vidal, that the latent image in a plate was not destroyed by potassium bichromate. He had found, however, that potassium bichromate, as well as other oxidising agents, produced a change in the reduction product which delayed or prevented the development of this portion. He was led to the view that the action of light produced (a) a product which was not attacked by the oxidising agents, and which could be removed by the fixing bath; (b) a product which was rendered non-developable by the oxidising agents, and after oxidation was apparently removed by the fixing bath; (c) a reduction in the film which was not removed by the fixing bath.

The paper was followed by a discussion in which Messrs. C. E. K. Mees, F. F. Renwick, T. Thorne Baker, and the chairman took part.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION. Meeting held February 21, Mr. A. Haddon in the chair. Mr. Archer Clarke lectured upon "Modern Printing Processes," in the course of which he reviewed the collotype and photo-litho processes, ferro-prussiate, and ferro-gallic and gelatino-bromide.

In the report of the L. and P.P.A. meeting of the 14th, in our issue of February 28, p. 149, there is an error in the developer formula. This should read "water, 20 oz." not "1 oz."

CROYDON CAMERA CLUB.—Mr. F. J. Terry, a careful and successful worker, gave last week an exposition on "Orthochromatism," simply and clearly worded. Amongst many orthodox expressions of opinion, the lecturer strongly urged the necessity of correct exposure, gauged by an actinometer, owing to the lessened latitude of the plate when screened. He had been through a maze of plates and screens, and by a process of evolution had settled down to the exclusive use of one plate in conjunction with a screen of "Filter Yellow K." This combination permitted instantaneous exposures with correction. He was a strong advocate of developments by time, the length of which only varied with the temperature, just sufficient light being allowable to see dishes, etc., no direct rays being ever allowed to strike the plate. If the Watkins system were adopted, then a lower factor should be taken for ortho' plates. Personally, he would diminish the usual factors by 25 per cent. It had been alleged that ortho' plates and screens killed "atmosphere" and "distance." With a correctly adjusted filter this was not the case, whatever it might be under other conditions. Perhaps the stiffest thing of all to adequately render was the true tonal value of a cloudless blue sky; with anything like correct exposure any clouds present were invariably recorded. In the discussion which followed, the temptation to debate the relative advantages of "ortho" over "ordinary" plates, a never-ending and somewhat unprofitable subject, was happily resisted. It was however pointed out that the utility of gauging exposure of screened ortho' plates by means of an actinometer was seriously open to doubt, owing to the fact that the plate was fully sensitive to a large part of the spectrum, to which the meter paper was comparatively insensitive. A meter paper with an extended range into the yellow and orange was badly needed, and a hint was thrown out that in the near future such a paper might be on the market. Mr. Terry's conclusion as to taking a lessened Watkins factor under the conditions stated, was endorsed, it being an established fact that the yellow rays gave a much steeper gradation than the blue, which, with the ultra-violet, mainly affected the ordinary plate. Consequently, for a given degree of contrast, shorter development was necessary with the ortho' plate. In this connection different brands of ortho' plates varied amongst themselves, and each probably required a different factor.

COLOUR-PHOTOGRAPHY IN OPEN COMPETITION.—At the exhibition of the Birmingham Photographic Society, a bronze medal is awarded in the Open Section to Mr. H. J. Comley for a three-colour print, "Nuts and Oranges." Mr. Comley, as Secretary of the Society of Colour Photographers, is known to be interested in securing special recognition of colour work at photographic exhibitions.

## Commercial & Legal Intelligence.

PHOTO REPRODUCTIONS, LTD. (Nottingham).—£450 5 per cent. debentures, created and dated February 4, 1907, charged on the company's property, present and future, including uncalled capital, have been registered.

EASTMAN KODAK COMPANY OF NEW JERSEY.—The usual quarterly dividends of 1½ per cent. (being at the rate of 6 per cent. per annum upon the outstanding Preferred Stock, and of 2½ per cent. (being at the rate of 10 per cent. per annum) upon the outstanding Common Stock, have been declared by the Eastman Kodak Company of New Jersey, payable on April 1, 1907, to stockholders of record on February 28, 1907.

CANVASSING FRAUDS.—At the Marylebone Police Court last week a man, named E. Jones, of Kimberley Road, Edmonton, was charged on a warrant with obtaining 6s. by fraudulent pretences from Margaret Coghlan, a cook, at 17, Froggnal, Hampstead.

The prosecutrix said that prisoner called at the house of her mistress on February 4, and explained that he had started in business as a photographer in Oxford Street, and would be opening two days later. He produced a coupon and said, "This is my coupon, and if you buy it for 3s. you can have a dozen cabinets worth 10s. 6d., and pay 6s. 6d. at the studio when sitting." She agreed to buy the coupon, but when she returned to the door, after getting the money, he said, "I'll tell you what I'll do. If you pay 6s. now you will only have to pay 4s. 6d. when sitting, and I will give you an enlargement with the dozen cabinets if you will allow me to put one in the window." She accordingly paid him 6s., only to discover when she went to the address in Oxford Street that he was not in business there for himself at all, and that she had been defrauded. She found, however, that he had been employed by the photographer carrying on business there, but was discharged last October.

Mr. John Mallia, the photographer referred to, said he discharged the prisoner in consequence of the many complaints he received about him. Since then hundreds of servant girls who said they had paid him money had called at his premises, and had completely disorganised his business; in addition to which he had received many letters of complaint.

Detective-Sergeant Ballard stated that when arrested the prisoner asked what harm he had done, and said he was authorised to receive 3s. on the coupons, so he did not see that he had committed any fraud.

The prisoner now stated that if it was a fraud he was not aware of it. He pointed out that he had a sick wife and five children in a dreadful condition, and he himself was starving; and on these grounds he asked that he might be allowed out on bail. Prisoner was remanded.

FENRIS FILMS.—According to the "Financial News," of Friday last, great things are expected of the Fenris film business, the introduction of which on to the Paris Bourse is to take place immediately. We omit the excursions of our contemporary into the classical derivation of the word "Fenris," but it is interesting to state that the company was formed in 1906 in London, with a capital of £100,000, of which £22,000 is intended to be reserve. Its objects is the working of a photographic film, of which the entirely new principle of manufacture will allow celluloid to be done away with and the cost of production to be considerably reduced, whilst offering at the same time considerable advantages over photographic films manufactured at the present day.

Fenris films are manufactured in France. By a special agreement the company which is selling to the Fenris Company its monopoly and license has reserved to itself the manufacturing of the films. This arrangement is believed to favour the Fenris, as it has no special industrial organisation—always a somewhat risky undertaking for a new affair to consider. The company is thus enabled to provide for an output proportionate to the orders in hand, so that it does not apprehend any difficulties of manufacture nor interruption, nor upkeep of a factory. The contracts which have been arranged are stated to offer sufficient guarantee for the Fenris Film Company to be able to reckon on a regular production and manufacture.

The Ferris Film Company states that it has taken measures for fully output of 3,000 metres, which may be raised to 10,000 metres more. The figure of 3,000 metres has been mentioned, as the cards now in hand are officially stated to amount to about 3,000 metres per day; but it can be increased according to requirements. This figure is, consequently, regarded as but a minimum. The large photographic trading firms of Paris require as much as 50,000 metres per day. Under these conditions the market of the product considered by the company to be fully secured. The company has established in London two sale departments—one in the City the other in the West-End—and these two offices, with the help of the customary means of advertising in England, already enjoy important turnover. The Ferris Film, Limited, intends also to have depôts in Paris, Berlin, Vienna, Naples, Brussels, Barcelona, Madrid. This organisation has been the subject of the closest scrutiny, and in view of it the promoters claim that they have secured the assistance of well-known commercial and photographic experts.

## Correspondence.

- \* *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*
- \* *We do not undertake responsibility for the opinions expressed by our correspondents.*

### PLATES AND FILTERS FOR PHOTO-MICROGRAPHY.

To the Editors.

Gentlemen,—Since writing the small booklet on the "Selection of Plates and Filters for Photo-micrography," I have found that a considerable amount of work on the same lines had been previously done by Dr. E. J. Spitta. This was published in "Photography" (No. 25, 1904), and also in his book on "Photo-micrography." The idea of screens giving exact contrast to the stain is there pointed out and should certainly have been noted by me. The omission was due to "sheer ignorance, nothing else."—Yours, etc.,  
C. F. KENNETH MEES.

### RECOVERING PLATINUM RESIDUES.

To the Editors.

Gentlemen,—In reference to the letter of Mr. G. T. Harris in your issue of February 8, I may say that my experience of protoplasmic iron has been that it is not a suitable reducer for platinum recovery. I cannot say why but I believe Mr. Harris's experience is that of others. I should suggest to him that he tries the zinc and acid process. It is all the better if the solution is warm at the time the zinc and acid are added. The latter may be hydrochloric, but sulphuric is equally effective, and cheaper. In either case there must be a copious evolution of gas. Any zinc which remains at the end of the reaction may be used again, but at the care should be taken to scrape off any adherent platinum.—Yours truly,  
"STATU NASCENDI."

### PROFITS ON PICTURE POSTCARDS.

To the Editors.

Gentlemen,—I read with interest Mr. Corkett's letter in your last issue. From some experience, I think his critique on the estimate is in the main correct, though I question if many stationers outside large towns visiting centres get through 100,000 a year. The large wholesale producer, anyhow, gets the cream. However alive the local photographer may be, or willing to supply the stationers of his district (and rightly he must keep there if the man in the next town is too far to go with his stationers), he finds himself handicapped by the wholesaler, who, if they cannot buy a set of negatives off-hand locally, will hire someone to take them. And here comes the question of a reasonable price to charge a firm you know will be able to undersell because he works over a larger area, and can thus give larger

orders to actual producer, perhaps in Germany. It would be interesting to know what Mr. Corkett thinks a reasonable price.

He says the photographer was always adverse to the postcard. Why? If he had a view-selling trade at all, he knew it would be seriously affected. This has resulted.

Stationers who could sell for you, varying according to place, from £50 to £150 worth of views during the season, cannot now sell a tenth of the amount, and if the photographer prints his own P.P.P. cards he has to employ treble the labour to produce an equal profit; and if he buys at best rates the cards that sell from 1d. each, now often three for 2d., he has to invest on spec. a larger capital if he is to net a proportionate profit.

As to ordinary portraiture, the photographer has himself to blame if he supplies postcard portraits at much, if any, below his terms for other work the same size. Unfortunately, photographers in a town do not hold together; if they combined, the public would be obliged to pay better prices than they now do in many places for such.

Not only has the sale of portraits of celebrities, but the prices charged for amateurs' work generally, have cheapened photographs in the eyes of the public.—Yours,  
PROFESSIONAL.

## Answers to Correspondents.

- \* *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- \* *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*
- \* *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

G. J. Heaton, 257, Lavender Hill, Clapham Junction, S.W. Two Photographs of the Rev. W. J. Carey.  
H. J. Hole, Swain Street, Watchet. Photograph entitled, "A West Country Joke when Wife is Away."

### DRAWING REGISTERED:—

E. F. Symmons, 3, Clifford Street, York. Drawing entitled, "Angram Performer."

GLAZING POSTCARDS.—Would you kindly inform me the quickest way to glaze postcards? Do you suggest a burnisher? If so, where could I obtain one best for this purpose?—H. P.

Squeegeeing from plate glass is the only commercial process for quantities. The prints should be given a short bath of alum before the final washing, and plates are well polished with French chalk. If the squeegeed prints are dried by a current of properly warmed air, they can be stripped off within three-quarters of an hour.

TELEPHOTO.—The "Adon" used with another lens gives about double the focal length, but the combination does not provide covering power quite equal to defining to the corners of the plate. But used alone, the Adon gives any desired degree of magnification and covering power. A useful rule is that its equivalent focal length equals twice the camera extension plus  $4\frac{1}{2}$  inches. That is to say, with 15 inches extension, you can get a focal length of 35 inches. No telephoto lens will give the same critical definition as an anastigmat used alone, and rapidity also falls off as focal lengths over 10 inches are obtained. We advise you to get an elementary work on tele-photography, such as Dr. Deller's (Dawbarn and Ward, 1s.)

SODA SULPHITES.—Is there any advantage, or the contrary, in using half the quantity of anhydrous soda sulphite and anhydrous soda carbonate, instead of the full amounts of crystal soda

sulphite and crystal soda carbonate given in development formulae—Toxo.

The anhydrous soda sulphite is said to keep better in the dry state. The carbonate requires to be tightly bottled, as it loses strength by absorption of water. There is no difference, in either case, when the substances are dissolved.

**LIMERICK.** There are none. The manufacture is done in America and Germany. You had better apply to Messrs. Guitermann and Co., 35-36, Aldermanbury, E.C.

**COPYRIGHT.** I have photographed for my own use for publication on postcards all the surrounding views, and have been selling them. I now find that a grocer here is selling my views, reproduced upon the penny cards (ink-type). 1. Have I any power to stop the sale of them, I holding no copyright? 2. If I can stop the sale, can I compel the shopkeeper to stop selling them, and hand over to me the cards he has? 3. Should I have to find out who published them, and proceed against them?—**ANXIOUS.**

1. If you register your copyright in each photograph at once you can stop further sales by anyone. 2. You can take action for the delivery to you of the infringing postcards. 3. It is not necessary.

**PINATYPE.**—1. Is there any benefit in the final result in drying tricolour carbon tissues, pinatype print plates, etc., by the method of dried warm air sucked through the drying box by means of an electrically-driven fan, as compared with the slower method of air-tight box and calcium chloride? I mean for small batches of say twelve half-plates. I have constructed a wooden drying box, properly lined with zinc, which will hold twelve half-plates, with 4in. space between each, size of box 29in. x 18in. x 15in. 2. What quantity of calcium chloride is sufficient for this size box? 3. What size pipe for inlet and outlet for working this box with electric fan? Having no installation on the premises, could I work the fan with an accumulator or batteries?—**FRANCIS B. WILLIAMS.**

1. There is no advantage as regards the pinatype print plates, nor will there be if alcohol is used in the sensitising bath for the carbon tissue, as suggested on page 9 of our issue for February 1. 2. The more calcium chloride used the more rapid the drying, and as the damp salt can always be re-dried and used again, there is no need to be sparing with it; still 2 ozs. in small pieces will be ample for the given number of plates. 3. About a four-inch inlet and a three-inch outlet would be sufficient. The fan could be worked with accumulators, but assuming that there is any reasonable supply of water, a small Pelton water motor would be much cheaper and more convenient.

**TIME DEVELOPMENT.**—1. Please give a formula of pyro-soda developer, in ounces and part ounces, suitable for time development. 2. Kindly state if the time is taken up to the moment the image appears, what factor should be used to complete development at a certain temperature. 3. Give instructions for diluting the developer (and temperature) for stand development to last two hours.—**P. C. SMITH.**

1. The following is recommended by the Kodak Co. for use with the development machine:—

Pyro .....	50 grs.
Sulphite of soda .....	500 grs.
Carbonate of soda.....	200 grs.
Water .....	40 ozs.

Use at 65 deg. Fahr.

2. In the case of pyro, the factor depends on the strength of the solution in pyro. Mr. Watkins, in his "Manual," gives (for pyro without bromide) a factor of 12 at 2 grs. per oz., of 10 at 3 grs., and 3 at 4 grs. See the "Almanac," p. 962. 3. We have no experience of pyro for such prolonged development. You had better try dilution of the solution to about 1-10 of a grain of pyro per oz., and add extra sulphite to prevent stain.

**RESIDUES, ETC.**—1. What should be the average cash value of silver recoverable from waste silver paper per pound, the paper being mostly Paget and Wellington? 2. Also in sending parcel to refiners, would you advise burning the paper first and forwarding the ash? 3. Is it generally known that enlargements can be made from any size negative by artificial light without a condenser, and if so by what methods have results been obtained?—**J. W. H.**

1. It is impossible for us to say. 2. It is a matter of convenience. In accumulating enough P.O.P. clippings and prints to be worth recovery, the storage room and carrying become considerable; hence it is better to burn the paper. 3. There are several methods: such as reflectors—the burn of magnesium ribbon behind the negative—but none equal a condenser.

**BUILDING A STUDIO.**—1. I am shortly having a studio built. Will you kindly say which is preferable, a north or east light: I have either? 2. Also will the following dimensions be suitable 30 x 16? 3. Where can I obtain plans of a good studio?—**B.**

1. Either light is a good one for working in. With a north aspect, however, the light is more uniform throughout the day than it is with any other, and requires, perhaps, a little less skill in working. With a north light, as frequently used, there is a great sameness in the lighting in all the portraits taken. That, however, is not due to the light but to the work. 2. Yes, very suitable indeed for all purposes. 3. In Bolton's book, "The Photographic Studio and its Construction," published by Marion and Co., Soho Square, price two shillings, there are several different designs for studios, and hints on the construction.

**P. S. (Mullingar).**—They are the same. The qualities vary with thickness. We should advise you to ask for a set of our sample pieces.

**W. B. WOOD AND OTHERS.**—In our next.

**F. E. G.**—There is no reason why the focal plane shutter should not answer your requirements. In fact, it, or a good diaphragm shutter working up to 1-100 or 1-150 of a second, is the best thing for such work. In regard to the lens, there are a number of first-rate ones working at  $f/4.5$  to  $f/5$ . Consult the makers' lists in the ALMANAC and the recent reviews in our columns.

**J. S. (Wolverhampton).**—See the article on p. 82 of our issue of February 1 last.

**PHOTO TYPE CO.**—Moore, De Saulles, and Co., Wordsley, near St. George's bridge.

**REVERSING NEGATIVES.**—1. Plate was placed in slide reversed error, glass side to lens; how can I rectify? 2. Some fifty years ago I used to obtain a sensitised paper, green, for making light effects; is it to be had now, where, and if in postcards?—**MIRANDIDIE.**

1. You can strip the film by the method on page 972 of the ALMANAC, but the safer plan is to make a transparency: copy this in the camera so as to get a negative with the desired reversal. 2. Not that we know of, except the tinted transparency papers for use with the carbon process. You cannot adopt a better method.

**RETOUCHING** (Reply to J. H. J.)—Had you not informed us that you only commenced retouching in November last we should have given you credit for several years' experience, for only in the time can the average retoucher acquire a soft grain or texture effect; although a marketable smoothing up may be attained in a few months. Be careful in the treatment of the nose, also fine up a bit more for modern requirements, especially printing on glossy papers.

**NOTICE TO ADVERTISERS.**—Blocks and copy are received only to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears on the front portion of the paper.

## SUMMARY.

reproduce a portrait said to be the first ever taken by terre. (P. 178.)

r. Arthur Payne now uses pinacyanol as the sensitiser in making his theatrical snapshots during the ordinary public performance. (P. 173.)

r. Mees and Mr. S. H. Wratten have examined the results obtained with suggested systems of applying a limited amount of developer to the plate. (P. 172.)

table of failures and remedies in carbon printing, of German origin, supplies some useful hints to those using the process for colour work as well as monochrome. (P. 176.)

system of full-size focussing has been recommended, in which image formed on the white blind of a focal-plane shutter is reflected in a mirror up to the negative. (P. 170.)

American worker relates his experience of ozobrome in decorative pottery. (P. 175.)

Further cases of canvassing frauds were heard at the London courts last week. (P. 185.)

country professional relates his experience of postcard production and publishing. (P. 186.)

refer to the literature dealing with the action of chromic acid on the latent image. (P. 171.)

Keartons have completed an exhaustive work on British photographic eggs, illustrated throughout by photographs. (P. 181.)

German author lays stress on the importance of proper tone background in order to give the desired effect of recession. (P. 176.)

## EX CATHEDRA.

### Enclosed Arcs and Enlarging.

The composition of the light from an enclosed arc-lamp, that is to say its richness in the ultra-violet light, may give rise to a difficulty which an enlarger may easily be at a loss to ascribe to its real origin. The case has been mentioned to us by no less than three enlarging firms within the past few weeks, and we may therefore assume that it is of sufficient general interest to refer to. The trouble in each case was want of sharpness in the enlargement, although the image on the easel was perfectly sharp. In one instance it became noticeable as soon as an open arc was replaced by one of the enclosed type; in another it did not manifest itself until an old pattern R.R. was replaced by a modern anastigmat. In either case the cause is the difference between the focus of the ultra-violet rays and that of the visual rays. The correction usually adopted by opticians applies to rays about 4,340 in the blue and 5,890 in the red. The use of a light source containing a great deal of the ultra-violet light of wave-length about 3,400 naturally upsets the efficacy of this correction, and for that particular light the lens, although perfectly corrected for ordinary work, is actually non-achromatic. There is, however, a remedy for the defect in the shape of a very pale yellow screen which will cut out a great deal of the ultra-violet. A screen of the new dye "Filter Yellow K" may be used for this purpose, but it must be very weak in colour, otherwise the length of exposures in making the enlargement will be increased and the contrasts in the results will be intensified more than may be desirable. The active bleaching action of the ultra-violet rays should be borne in mind, and the filter checked occasionally. A screen of asculin would, no doubt, be better than one of "Filter Yellow K," except that the substance is darkened by light.

### Science for the Amateur.

We are glad to find that among the journals appealing to the less advanced amateur worker there are still signs of a determination not to ignore totally the important scientific papers of which, if they appear to us to deserve it, is our custom to publish a full translation. We write this apropos of the commencement in "Focus" of Wednesday last, of a page headed "Progress of the Month," wherein the microscopic researches of Dr. Scheffer, Dr. Homolka's indoxyl developer, three-colour cameras, and other matters are treated popularly yet exactly. This new feature is in the capable hands of Dr. S. E. Sheppard, whose influence on the staff of our contemporary will possibly check such lamentable incidents as a recent reference to the inventor of Velox and author of numerous papers as "a Dr. Backlandt."

ards would come the development with the silver intensifier, as described by Mr. Sterry. We doubt the practical use of this pretty scheme, though it possesses possibilities in the hands of secret commissioners or the modern novelist of sensation. Mr. Hall Caine should certainly make a note of it.

## THE ACTION OF CHROMIC ACID UPON THE DEVELOPMENT OF THE LATENT IMAGE.

The paper read by Mr. John Sterry before the Royal Photographic Society last week was a resumption or continuation of a previous one read before the same body in 1904, and has conclusively established the fact that the action of light upon the sensitive halides of silver is such that it is not subsequently destroyed by chromic acid. Whether we assume with Mr. Sterry that development is arrested into primary and secondary actions or not, there is no question that we have an extremely valuable method in practical work. The basis of the whole system, which to our mind has been most conclusively proved by Mr. Sterry's last paper, is that, whatever may be the action of light upon the sensitive silver salt, there is left behind, after fixation, or after treatment with chromic acid followed by fixation, a something upon which it is possible to deposit metallic silver, and that, however faint the light action, a nucleus persists.

The subject is one which has been attacked in many quarters and in various ways. The fact that it was possible to physically develop an image on a collodion plate after fixation, when to all appearances nothing but a perfectly structureless film remained, was first observed by Reichenow in 1858, and confirmed in the following year by Reichenow and Bayard. It is obvious, then, from this fact that if there is no "silver germ" left, there must be set up by the localised stress, strain, or condition in the vehicle which is sufficient to form nuclei for the aggregation of nascent silver; and, further, that this X, or unknown, produces an image which may without exaggeration be taken to be equal to that obtained by primary development, that is, development of the light-affected silver halide itself. The fact that this was observed with collodion plates that X may be independent of the vehicle.

The first experiments with gelatine plates were made, I believe, by Franz Kogelmann, whose results appeared in a little-known work, "Die Isolierung der Substanz des latent photographischen Bildes" ("The Isolation of the Substance of the Latent Photographic Image"), published in 1894. It is impossible to follow his experiments in detail; but one, by means of which he claims to have proved that it is not the action of bromine on gelatine that gives rise to the image, is interesting, because it leads us to the conclusion that when bromine were set free during an exposure in sufficient quantities to combine with the gelatine, this bromine would—being well known that gelatine is tanned by bromine—is not the cause of the developable image. Kogelmann exposed two plates under a scale—the one fixed, or, to use his own term, "extracted," with hyposulphite, the other with sodium sulphite. Both were washed and then exposed for three hours to gaseous bromine. On development with iron acid developer, an image was obtained identical in all respects with that on similar plates not treated with bromine. Kogelmann comes to the conclusion that the invisible X is a "silver skeleton" of the substance of the latent image.

Mr. Eder has, of course, examined the question of the constitution of the latent image, but mainly by means of chromic acid. His use of chromic acid has been principally

confined to the destruction of solarisation, and has proved that, although 0.1 candle-metre-seconds was necessary to produce the faintest light action, and that fifty to one hundred times this quantity gave dense high-lights, yet it was possible by the use of chromic acid to destroy the solarisation caused by 1,000,000 candle-metre-seconds. Lüpke-Cramer has also investigated the action of chromic acid on emulsions generally, but as many of his conclusions do not differ materially from those of others, we need hardly enter into details.

Mr. Sterry's experiments have been made not only with the latent image produced by short exposures, but also with the printed-out images on gelatino- and collodion-chloride papers, also with printed-out images on gaslight papers and lantern plates on very rapid plates and on dry collodion. The visible images thus obtained were treated with chromic acid, fixed, and then physically developed with the well-known sulphocyanide silver developer or intensifier of Mr. J. B. B. Wellington. It is interesting to note that in all cases the colour of the resultant image was black, either pure, rusty, or greenish in hue.

In the case of P.O.P., every trace of an image disappeared after treatment with chromic acid and fixation, yet a vigorous black image was obtained by physical development. Here, then, we have a state of affairs almost analogous to the case of the latent image on dry plates, which might lead us to the conclusion that the latent image is but an elementary or incipient printed-out image—that is to say, the substance of the image is in both cases of a like chemical nature, a view which is also held by some authorities. There is also a still further analogy between the dry plate and the printing-out paper, and that is that both can be colour-sensitised with the same dyes and for approximately the same region of the spectrum. This was proved by Dr. Andresen's experiments and patented process of colour-sensitising normal silver chloride photographic paper, as well as by Eder's tests as to the distribution of the blackening by printing-out and that obtained by development, the two curves being approximately parallel with corresponding maxima and minima.

The practical application of the chromic acid treatment has already been found useful in the production of soft harmonious prints on bromide paper from very harsh negatives. It is only necessary to expose fully for the dense high-lights, neglecting the shadows, to treat with chromic acid, wash and develop, when a perfectly harmonious soft print is obtained. The faint impress of light under the densest parts of the negative is not lost, but the otherwise excessive density under the shadows is reduced, so that there is finally a much longer scale of gradation.

A TRAVELLING PHOTOGRAPHER, named George Douglas, was sentenced at Dartmouth last week to a month's hard labour for stealing an overcoat. He had a previous conviction at Belfast against him.

ILLINGWORTH PAPERS.—Messrs. Thomas Illingworth, Willesden Junction, N.W., inform us that they have been awarded the gold medal, being the highest award, for their exhibit of "Carbon," "Bromide," and other prints, at the exhibition held in Turin during January and February.

PHOTOGRAPHIC SURVEY OF SURREY.—The annual meeting will be held in the Council Chamber, Town Hall, Croydon, at 4 p.m., on Saturday, March 16, 1907, when the Mayor of Croydon will give an address, and the report of the Council and the accounts of the year ended December 31, 1906, will be submitted. The meeting is open to all interested in its work and aims, and an exhibition consisting of a representative selection from the 2,340 prints already in the survey collection, will be arranged in the Lecture Room, Town Hall, Croydon.

## DEVELOPMENT WITH INSUFFICIENT REDUCER.

THERE have been various methods proposed at intervals for developing a plate in such a way that the reducer should, either locally or universally, be exhausted before reduction was com-

Fig. 1.

Fig. 2.

Fig. 3.

plete, so that the extent of development should be determined, not by exhaustion of the latent image, but by exhaustion of the developer itself.

Possibly the oldest of these methods is that given by Abney in his "Instruction in Photography," of removing a plate from the developer upon the appearance of the image, and allowing development to proceed by means of the developer in the film.

Another method was suggested by D. W. Hart, in his patented method of development, by squeegeeing a sheet of gelatinous paper soaked in developer on to the surface of the plate.

Yet another method has been recently brought forward from

Fig. 4.

Log. E.

Fig. 5.

Germany, under the name of "Plane-development." And this appears to us to be a fundamental misconception underlying these and other methods of modifying the plate curve. The idea seems to be that a photographic plate gives too much density when acted upon by intense lights, and that, owing to the fact that this density is beyond the printing scale of effect of over-exposure results. If this idea were true, then it would surely be easy to remedy the matter. All that would be necessary would be the production of plates incapable of giving

eat densities, by reason of the poverty of their films. But  
rely, the effect of over-exposure is due to the fact that with  
creasing exposure a plate does not give sufficient density,  
giving flat results, and requiring greater development to obtain  
the necessary contrast in the high-lights, which in its turn  
produces a total contrast beyond the printing range.

Thus in the figure (1),\* suppose that P represents the printing  
range of a paper, and that in consequence of the over-exposure  
of a plate A, that plate must be developed to the steepness shown  
in order that the contrast in the high lights shall be sufficient.  
When this plate, if developed by a method in which the high-  
lights are restrained by exhaustion of the reducer, will give a  
result similar to that shown in B. If, however, the plate had  
greater latitude, it could have been developed as shown in C,  
giving sufficient contrast in the high-lights, and yet keeping  
within the printing range.

In order to determine the efficacy of these methods of restrained

\* This figure is purely illustrative and imaginary, not measured.

development, we have made a series of measurements of the  
methods given above.

Fig 2 shows the result of Abney's method, which is quite  
effectual in accomplishing its object.

Fig. 3 shows Hart's method. In this the effect, of course,  
depends upon the strength of developer employed. Various  
degrees are shown.

In plane-development, the plates were developed in an  
absolutely horizontal position in Hübl's glycin developer,  
diluted. It will be seen from Fig 4 that we have found the method  
to produce little or no departure from the normal. We do  
not know the cause of this, as no marks indicating disturbance  
of the developer were produced at all, and various strengths  
of developer were used. Probably the most effectual method of  
producing this kind of modification of the plate curve is to  
employ ferrous oxalate developer, containing thiosulphate. An  
example is shown in Fig. 5.

S. H. WRATTEN.

## THEATRICAL PHOTOGRAPHY.

It has been very gratifying to me to notice the interest which  
has been taken in this branch of photography since I first  
published the results of my experiments in this direction, and  
notably its adoption by the press photographer, for photo-  
graphs have already been published by the "Daily Mirror"

stage scenes taken during the public performance, pre-  
sented by the method which I published in detail in  
the BRITISH JOURNAL OF PHOTOGRAPHY, July 6, 1905, under the  
title of "The Camera and the Play." I had previously indicated  
the use of plates bathed in orthochrome T. dye for this work in  
"Photography," May 28, 1904.

It has therefore occurred to me that it may be of interest to  
those engaged in this work if I bring the description of my  
methods up to date, it being understood that this paper is sup-  
plementary to that which has already appeared in this journal.

### Pinacyanol Sensitiser.

In the first place, I have abandoned the use of orthochrome T.  
dye, substituting for it a 1 in 50,000 solution of pinacyanol,  
which not only confers increased sensitiveness upon the plates  
bathed in this solution, but also makes them more sensitive to  
red light than to blue light when tested with a Chapman Jones  
colour sensitometer by the light of a standard candle. Candle  
light was used, because I am of the opinion that the quality  
of this light may be fairly accepted as an average standard of  
the quality of stage lighting. An orthochrome T. bathed plate  
tested under similar conditions gave a result in which the red and  
blue sensitiveness of the plate were approximately equal, and  
when it is considered that the average light reflected from the  
stage is strong in the red and yellow rays, it will be realised  
why the great red sensitiveness of a pinacyanol bathed plate is  
of such value in stage photography.

The relative speeds of both kinds of bathed plates, and also  
of an unbathed plate, were roughly estimated by means of a  
Chapman Jones plate tester to candle light, and whilst allow-  
ances must be made for the light absorbent qualities of the  
sensitometer when comparing the readings of the unbathed  
against the bathed plates, this will probably not seriously affect  
the comparative value of the readings obtained on the bathed  
plates. I now use Mawson's Felix plates for bathing

Read.

"Felix" unbathed .....	16
,, bathed with orthochrome T. 1 in 50,000	22
,, ,, ,, pinacyanol 1 in 50,000.....	24

It is obvious that the gain in speed by yellow light is consider-  
able when pinacyanol is used, so much so in fact that I have  
been able to obtain a good negative, when the stage was illumina-  
ted by yellow light only, with a focal plane shutter exposure of  
about 1-7th to 1-10th of a second with a lens working at  $f/3$ .

When preparing these bathed plates, my procedure is to bathe  
"Felix" plates for three minutes in the following solution,  
which should not be used more than once:—

Pinacyanol (1 in 1,000 alcohol) .....	2 c.c.
Distilled Water .....	100 c.c.

The plates are then well washed for three minutes and wiped  
surface dry by means of a pad of damp cotton wool, or damp  
washleather, and then dried.

### A Green Safe-light

For this work I find it is quite safe to use a faint green safe  
light, which may be of such a low luminosity that it is impossible  
to read the figures on a Watkins eikronometer (the small develop-  
ing clock) when it is held close to the lamp, but which gives  
sufficient light to enable the operator to work in comfort, even  
at some distance from the lamp. This does not necessarily mean  
that the pinacyanol bathed plate is insensitive to green light,  
but rather that the physiological effect of green is much more  
useful than any other colour. For instance, the eye itself is  
rather insensitive to red, so that it naturally follows that it is  
necessary to use a considerable amount of red light in order to  
be able to see by it at all. Dr. Louis Bell, quoting Sir William  
Abney, states that: "Starting with the normal curve of lumino-  
sity, the peak of the curve being one candle power, the light at  
B (in the spectrum) would disappear if the illumination were  
reduced to .01 of its initial value, that at C at about .0011, at  
D .00005, at E .0000065, at F .000015, and at G .0003." So that  
it follows that the power of the green light may be reduced to a  
lower degree than any of the other colours and still retain its  
usefulness as an illuminant. Or to express this differently, if  
the luminosity of three safe lights, red, yellow, and green, were  
adjusted so that they are equally useful as illuminants, the  
candle power of the green light would be less than that of the  
yellow, while the red light would have to highest candle power  
of the lot.

Do not, however, be tempted to use an unnecessarily large  
amount of green light, but keep the light turned down to the  
lowest point consistent with its value as an illuminant, and  
shade the plate as much as possible even from the action of this

faint light. It is hardly necessary to explain that the eyes are more sensitive to this faint light after the operator has been in the dark room for a few minutes, so that he should make his preparations by means of a fairly strong green light and then lower the light when the plates are bathed or developed.

My dark-room lamp is fitted with a glass tank of an internal thickness of one inch, which is filled with the following solution :

GREEN SAFE LIGHT.

Acid green .....	2 parts.
Naphthol green .....	2 "
Tartrazin .....	15 "
Water, distilled .....	300 "

Dilute one part of this stock solution with twenty-five parts of water, and use it in a one-inch thick cell. A sheet of ground glass should be placed in front of the safe light in order to diffuse the light.

Exposing Plates Wet.

It is not really necessary to dry the plates after they are bathed and washed, for I find from sensitometer tests that there

Miss Jose Collins in the pantomime "Aladdin," Tyne Theatre, Newcastle-on-Tyne. Hand camera exposure, with focal-plane shutter working at about one-tenth of a second. Portrait lens at  $f/3$ . Scene painted in yellows and reds, and lit by yellow light. Taken during the public performance.

is no appreciable difference whether the plate is exposed in a dry state, or immediately after the surplus water has been wiped from the surface of the plate in the manner already described. Possibly in the case of the wet plate a trifle more density is obtained with equal development than when the plate is exposed dry, but otherwise there appears to be no difference in the results. I have also tested the use of wet plates in the theatre, and I find that they give good results after they have remained

in the dark slide for forty-eight hours. Three hours elapse between preparing the plates and exposing them in the theatre, and forty-five hours between exposure and development. Contrary to what might be expected, these wet plates work free from fog and more cleanly than plates which have been dried rapidly. It is advisable to soak the wet plates in distilled water for ten minutes before they are developed, so as to avoid appearance of uneven density, due to uneven development, caused by the plates partially drying in the slides. It is, of course, better to use the plates when dry, and this I recommend whenever it is possible to prepare them in time to allow of drying before they are placed in the dark slide, but it may be useful to know that on special and unforeseen occasions, they may be successfully exposed without waiting for them to dry.

The edinol developer that I recommended for use in my previous paper was made according to the formulae given by the makers of edinol, but it apparently contains an unnecessarily large quantity of sodium sulphite, and I find that edinol may be successfully used when compounded as follows:

EDINOL DEVELOPER.

Sodium sulphite, cryst. ....	1 oz. avoiz.
Edinol .....	50 grains.
Sodium carbonate, cryst. ....	1 oz. avoiz.
Distilled water .....	10 fluid oz.

Dissolve the salts in the order given, and develop the plates for five minutes at a temperature of 75 deg. F.

Taking into consideration the great red sensitiveness of panchromatic cyanol bathed plates, and the preponderance of red and yellow in the average stage lighting, it ought not to be very difficult to obtain successful three-colour negatives of stage scenes with comparatively short exposure. Of course, they could not, at present, be obtained during the public performance except under very favourable circumstances, such as would arise when the theatre management would consent to hold the curtain for five or six seconds on the "call" at the end of the act, and the performers would pose for the photograph. Taking into consideration the value of colour stage photographs as an advertising medium for the proprietors, they might arrange for a special production in order to obtain a series of three-colour photographs of a pantomime or other spectacular play. I offer this idea to those who are interested in this work, and suggest that it is a proposition which might be brought before the notice of theatrical clients.

I again wish to record my sincere thanks to Mr. F. C. Sutcliffe of the Tyne Theatre, Newcastle-on-Tyne, for the courteous manner in which he has allowed me to make practical exposures in his theatre, and for the interest he has taken in the work I have in hand.

ARTHUR PAYNE.

ART FROM THE ARCTIC REGIONS.--Never before, and probably never again, could such an exhibition be possible as now occupies the Grafton Galleries, for only one man in a million could display the same evidence of enthusiasm triumphing over difficulties such as those suffered by Alexander Borisoff, of St. Petersburg. This artist, in response to a fascination felt for "the lands of mist and snow," made two Polar explorations, the latter made in company with two other Russians (a zoologist and a natural scientist), lasting a year and a half. He relates how his oil paints froze into solid lumps, even turpentine becoming useless; how he could sometimes only work with heavy fur gloves upon his hands, and then only by making rapid and energetic strokes. "There were moments when my hands were frozen, and refused service, my brush splitting with the cold." His results are marvels of colour and romance. He has painted with equal directness and subtlety the appalling infinitudes of ice and snow, the charming iridescence of the iceberg, the skies, from saffron to all but black, and the brilliant sun and blue shadows of the Arctic summer. All has been done under great privation and within call of death. Mr. Borisoff was, until the age of eighteen,

an unlettered peasant. He owes his chance in life to the Czar, the Grand Duke Vladimir, and Count de Witte, by whom he has been fostered and treasured. Two of the largest works are shown in a darkened room by artificial light; but they lose as well as gain by this display. He is strongest in his original sketches, which are impressively rough, and bear evidence of the moments of white heat enthusiasm which prompted them.

CYANIDE POISONING.—An inquest was held at Fleetwood last week relative to the death of Moses Livesbey, aged 46, photographer, of Bury. Dr. Preston expressed the opinion that Livesbey had died through poisoning by cyanide of potassium. The jury found that death was due to misadventure.

THE FALLOWFIELD SMOKER, to be held at Frascati's on March 18 is this year of special significance, as it celebrates the jubilee of this well-known photographic supply house. The advance proof of the programme shows us that an excellent evening's entertainment is to be provided under the chairmanship of Mr. F. W. Hindley. Tickets for the smoker may be obtained at 1s. each from Mr. J. C. Preece, 146, Charing Cross Road, London, W.

## OZOBROME FOR POTTERY DECORATION.

THE following notes on the ozobrome process by a contributor to the "Photo-Era" will doubtless suggest other applications of Mr. Manly's process to those interested in decorative applications of photography.

Personally, after reading of the ozobrome process, I was inclined to question its alleged miraculous powers. Having tried it, I unhesitatingly withdraw the first adjective. My first experiment was to try its applicability to lantern-slide work, and the results exceeded all expectations. Then I tried to get a carbon copy off a bromide enlargement. In this, success—after one ignoble failure—was also gained. I then thought of its adaptation to decorating pottery. Here some difficulties had to be overcome, but after a few failures and the exercise of a little perseverance they were successfully surmounted. The recital of these difficulties, and the methods of overcoming them, may be of interest to readers of this article, and, should they care to follow in my footsteps, they may shun the pitfalls where I have left a danger-post.

### Ozobrome on Porcelain.

I saw in a china-shop, one day, a plate with a beautiful blue border. My companion remarked that one of my photographs in blue carbon, placed in the centre, might enhance its beauty. The suggestion was dismissed as impracticable. However, when doing some lantern-slides by the ozobrome process the thought came into my mind, "Could not this picture, with equal facility, be transferred to the plate?" I could not get the thought from my mind except by one method, and that was a practical experiment. One of the ordinary household plates was requisitioned for the purpose. A gaslight print was taken from a negative, a circle mask, such as is used in lantern-slide work, being placed between the glass and the paper. It is well to leave a good margin of white around the circle. This performs the part of the "safe-edge," which is as necessary for ozobrome as for carbon. This was developed, fixed, and washed. When the hypo had been eliminated, the ozobrome pigmenting solution was mixed in the necessary proportions and placed in a dish. A piece of pigment plaster—marine blue was the colour chosen—the same size as the paper was cut and immersed in the solution till quite limp. It was then taken from the bath, placed face upwards on a piece of plate-glass. The print was lifted from the washing-water and placed on top of this, face downwards, of course, and gently squeezed into contact. The two together were then placed between sheets of damp blotting-paper and a sufficient time allowed for the print to transfer itself to the pigment—half an hour is about sufficient. (Some workers omit this and simply lay the print and pigment on a table and allow them to gain a certain dryness. This is all very well if they do not get too dry, for then there is a difficulty in separating them.) When it is thought that sufficient time has been allowed for the miracle to work, both are plunged into water, and under it they are separated.

### A Cause of Failure.

The pigment plaster was then squeezed on to the centre of the plate, a piece of dry blotting-paper was placed on top, above that a lantern-slide cover glass, and above that again as much weight as it was possible to put on. The "weight" I used was an enamelled basin full of water. Under this pressure the plate with the adhering pigment was left for twenty minutes to allow of proper adhesion. At the expiration of this time the weight and other paraphernalia were removed, luke-warm water was poured into the plate, and developments awaited with keen interest. No oozing of

the colour from the side of the backing-paper taking place within a reasonable period, slightly warmer water was used, and the desired effect took place at once. The backing-paper was then removed with ease, and the unaffected pigment came away beautifully. The picture was there all right, but as the dish was rocked to and fro to facilitate development the affected pigment began to peel off, and the experiment was a failure. Another was tried, and a longer time under pressure was allowed, but a similar result was to be chronicled. When the pigment plaster stuck nicely to glass without any substratum it was curious that it should not do the same to stoneware. A close examination, however, revealed the fact that there were inequalities in the surface, and this accounted for the failure.

### The Need of a Substratum.

It was quite evident, therefore, that a substratum was necessary, and the centre of the plate was coated with negative varnish, and when it was considered dry—about an hour afterwards—another trial was made. Failure was again in store, though the peeling off was not so pronounced. Another plate was coated with the varnish, and left for a night to harden. The same procedure recorded was gone through, and a beautiful picture resulted. The safe-edge, represented by the white margin around the pink, showed plainly, and it was necessary to get rid of this. A wet cloth was wrapped around the forefinger, and the circle was carefully gone round with the nail. The varnish came away quite easily at first, but as it began to dry it became more difficult. The finger with the cloth adhering was dipped in methylated spirit, and with that the remaining safe-edge came away quite easily.

A solution of alum was then placed in the plate, and left for half an hour. This acted as a fixing and hardening bath, and eliminated any traces of bichromate, which is one of the constituents of the pigmenting solution. The plate was then placed on a shelf in a warm room, and in an hour or two was quite dry.

The proceedings were now complete, but there remained the possibility of injury to the picture when the plate was dusted—washing this particular part would be fatal to its beauty. This was overcome by applying picture-varnish to the print. When applied, a rather streaky appearance presented itself, but in the drying process this vanished.

It is quite possible that if one could secure an unglazed plate the substratum of negative varnish could be dispensed with; but as to the pigment withstanding the heat necessary in the future glazing process, I am not in a position at present to say.

A word, in conclusion, as to the choice of colours. A sea-green pigment makes an excellent medium for representing a landscape; it can also be used for seascapes. Red chalk gives as correct a rendering of a sunset as is possible. But what I consider the best colour, and in which most of the experiments here recorded have been made, is marine blue. The pigment seems to have more depth than any others I have tried. Seascapes, which on the print look commonplace, have, in this colour, taken on a new beauty, and in snow scenes one can almost imagine he sees the sparkle of the snow, the substratum of negative varnish giving this effect.

W. FINDLAY.

## FAILURES AND REMEDIES IN CARBON PRINTING.

The following table is given in "Das Bild," and whilst it is specially drawn up for the tissues and stripping films as sold by the Rotary Photographic Company, it is obvious that in many cases it will also apply to ordinary carbon work. The letters T and F in the first column refer, the former to tissue on the ordinary paper support, and the latter to the stripping films,

Failure.	Cause.	Remedy.
1. The pigmented gelatine dissolves during sensitising, especially when touched with the fingers. T.F.	The sensitising bath is too warm .....	The sensitiser should not be warmer than 60 to 65° Fahr. It should be placed in a bottle and stood for a long time in running water or some pieces of ice should be added.
2. The gelatine runs in drying. T.F. ....	The drying room is too warm.	The room should be kept cooler or ammonium bichromate used with the addition of 25 to 50% of alcohol. See also No. 5.
3. The gelatine strips during drying. F. ....	The drying room is too warm and there is too much ventilation. Very dry weather.	The room should be damped by hanging up wet cloths, or be sprayed with water, 5% of glycerine should be added to the sensitiser.
4. The film shows reticulation during development and floats off the support, or it only adheres in the deepest shadows, and the half-tones dissolve. F.	(a.) The printed image is not laterally reversed on the gelatine. The film was placed with the gelatine in contact with the negative. (b.) The print is reversed. Too short exposure.	(a.) The celluloid must be in contact with the negative. (b.) Longer printing.
5. The gelatine will not dissolve even in the unexposed parts, in warm water. T.F.	Too long drying. (Damp air). The fumes of burnt gas or paraffin in the drying room. Fumes from an acid fixing bath. Old sensitiser.	Better ventilation or warming of the drying room, the hygrometer should not show above 70°. The drying room should be fitted with fans. Use an alcoholic solution of ammonium bichromate 15 gms., water 100 ccs. To every 25 ccs. of this stock solution add 25 ccs. of alcohol. This should be applied with a brush. Duration of drying 1½ to 2 hours. After use the sensitiser should be filtered. It should be frequently made fresh.
6. During development the highest lights alone dissolve. T.F.	Over-exposure. ....	Add to the developing water some ammonia; if details do not then show, shorter exposure is the only remedy.
7. The gelatine will not dissolve at all in hot water, and only shows relief. F.	Complete over-exposure .....	As for No. 6. If this is no use print one degree less on the actinometer.
8. As No. 7, it also shows reticulation. F. ....	As No. 7. The reticulation is caused by too hot water.	As for No. 7.
9. In the finest half-tones, transparent, round spots of different sizes and not coherent show, whilst in the shadows they are less transparent. F.	Crystallisation of the bichromate on the film through the use of too strong a sensitiser. Too long sensitising, insufficient blotting off of the same.	Use weaker baths. After sensitising blot off excess of solution with clean blotting paper. One minute's sensitising is enough.
10. The prints show dark places or streaks. T.F. ....	Excess of sensitiser was not blotted off and parts are thus more sensitive.	Excess of sensitiser should be carefully blotted or wiped off.
11. Development is difficult and irregular. F. ....	The excess of chromate not washed out before development.	The prints should be soaked for about 15 minutes, and the water changed twice.
12. The prints appear hard. See also 14. T.F. ....	Sensitiser too weak or too much ammonia added .....	For soft negatives use a 1 to 3% sensitiser with as much ammonia as will turn it straw coloured. For hard negatives a 4 to 5% should be used without ammonia.
13. The print is flat. T.F. ....	Too strong sensitiser .....	
14. The half-tones are eaten away, otherwise the print appears fairly good. T.F.	Developing water too hot, or too hot water was added. Too violent rocking during development.	The water should not exceed 80° to 97° Fahr. Too violent shaking should be avoided. A stronger sensitiser should be used.
15. The developed print shows slight reticulation. T.F.	Too hot water in developing .....	The temperature should not exceed 97° Fahr.
16. The celluloid will not easily strip from the picture. F.	The print is not dry enough .....	The remedy is obvious.
17. The transferred print is covered with shining round spots. (The support is a rough paper). T.F.	The transfer paper was not soaked long enough, or was not sufficiently squeegeed after transfer.	Rough transfer paper should be soaked for ½ to 2 hours in water, and just before use dipped into water at 125° Fahr. Stronger pressure on a soft support in a copying press.
18. The outlines of the transferred prints are covered with innumerable shining points. T.F.	The developing water was too cold and too full of air. The transfer paper was insufficiently soaked.	Use greater pressure and warmer soaking water.
19. The outlines of the individual prints do not exactly coincide in combination or three-colour printing. F.	One or other of the images was developed in too hot water so that one has expanded more than the other.	The constituent prints should be developed simultaneously or water used at the same temperature. The paper bearing the transferred print should be soaked longer.
20. The cemented prints do not adhere to one another when the print is dry. F.	The prints were not thoroughly cleansed from rubber. In transferring the gelatine was squeezed out during squeegeeing.	The prints should be thoroughly cleaned with benzole. After the gelatine solution has been poured over the print, the softened print should be carefully superimposed, and any air bubbles removed by gentle pressure with the fingers.

## THE PERSPECTIVE OF THE BACKGROUND.

No slight part, as every photographer knows, is played by the background in portraiture. The background can make or mar the total effect of a portrait, a fact which was recognised by painters long before photography was thought of for portraiture. The following notes on the background in portraiture, advanced by Herr Otto Mente in the current number of "Das Atelier des Photographen," should therefore be worth consideration.

After laying stress on the great attention paid by the old masters to the background, the author states that until the last few years the subject has been much neglected by photographers.

The first and most important question is the representation of the

background in its true position behind the shutter. Success in this important matter implies correct gradation of tone as regards the portrait and softness of focus. Slight fuzziness or "softness of focus," as it is preferably called, is an absolute necessity, for the reason that the human eye can only see sharply those objects on which the eye is focussed. The eye has no depth of focus, and everything in front and behind, or on either side of the object observed will not appear sharply defined. From the fact that the eye unconsciously focusses on the principal object, we see a portrait sharp, but the background and accessories will appear indistinct. This process of the living eye can be imitated by the lens when pro-

ly used, but we have now to deal with only the second factor causing the background to recede—namely, the correct relation (tone) of the background to the portrait.

### Aerial Atmosphere.

A background being always separated from the eye by a greater thickness of air than the sitter before it is exposed to the action of thicker layers of air, which latter exert the most pronounced action on tone effects. Let us consider a landscape with receding ranges of hills. The summits of the hills always become greyer and poorer in detail as they recede from the observer, and everyone who has not yet noticed the fact can at once convince himself by observing any subject, even a long street, in which there are receding planes. This phenomenon is caused by the innumerable number of dust particles which increase in proportion to the thickness of the air. These particles reflect light, and therefore brighten up the intensity of the shadows of distant objects. An open-air portrait will stand out from its background, the greater the distance between the two—that is to say, the less contrasts the background contains.

### The Dangers of Indoor Portraits.

In artistic portrait photography for some time it has been the fashion to photograph the sitter in ordinary furnished rooms. The man in this new portraiture should not be condemned in itself. Above all things, the person to be portrayed, if in his accustomed surroundings should lend himself more readily to artistic results. But there are difficulties. Whatever the lighting, accessories give too much contrast, even if so far removed from the sitter as to the one hand to give satisfactory softness, and on the other satisfactory definition of their form. As regards the use of a small top, a certain limit cannot be exceeded in practise for the sake of rapidity, and consequently the sitter and accessories must be liberally near one another, and the picture lacks repose. The lights and shadows of the background become more full of contrast than those of the portrait, and it is necessary to resort to subsequent retouching, such as doctoring the back of the negative to produce harmony.

Now that stereotyped accessories are banished from the studio, it is satisfactory to see that the painted backgrounds now made are more suited to the newer taste. More often, perhaps, walls covered with actual tapestry are now used. There is much to recommend this kind of background.

In the first place, the ordinary character of the room remains unchanged; in the second, any degree of softness of focus can be obtained without any trouble by merely altering the distance between the background and the sitter, and the distribution of the masses in the picture can be effected by alteration of the position to one side or the other of the tapestry.

### Focal Differentiation of the Background.

As a rule, however, we come to the conclusion that we can obtain better results with painted backgrounds than with natural surroundings, and we have the question as to how far from the sitter they must be placed in order to produce the necessary softness. The answer to this is very simple. In order to produce a constant ratio of softness of the background to a sharp portrait with lenses of different focal length, we must increase or decrease the distance between the two accordingly, as the focal length of the lens is shorter or longer. The stopping down of the lens is of little importance, as the aim in portraiture is naturally for the largest possible apertures, in order to obtain short exposures and roundness in the face and its surroundings.

Short focus lenses, with their greater depth of field, are not advisable, on account of the distorted perspective, so-called, which they give. Therefore, for individual portraits, we have only the longer focus lenses, with which the correct distance between background and sitter can be best determined in an empirical way. No formula can be given for this, as different cases require different degrees of softness. Before all things, must one decide as to whether the background shall be a background—that is, a complement to the portrait—or whether there is any actual connection between the sitter and the background. In the latter case, naturally, it is desirable to take a sharper and more definite representation than in the former; still, this is purely an æsthetic question, and further consideration of it would lead us too far.

### White and Black Backgrounds.

Undoubtedly even-toned backgrounds are the simplest to work, since there is no question of sharpness or softness, and therefore the dreaded "sticking" of the portrait to the background is impossible. Perfect black and perfect white are, however, extremely difficult to handle. The well known optical phenomenon that a small black square on a white ground appears smaller than a white square of similar size on a black ground warns us to take care. Actually one may often observe that in portraits on a perfectly black ground the head appears too large for the body. This appearance will be all the more prominent the greater the density of the negative. The reverse case is not so bad, but still even here there are other troubles, and the great white background warns us to take care. Actually the highest lights of the portrait and make these appear darker. A differentiation of the sparkling lights against the white background is no longer possible. At the time of the vignettéd bust pictures, which still survive in some places—a white, or at least a very bright, background was generally used, as it was thus possible to obtain a satisfactory shading off—into the background, at least—without any trouble. These pictures were, however, wanting in "plasticity," because the high-lights of the portrait could not be brought to their full value.

Abroad, dark backgrounds have again become the fashion, and the necessary design of the background is done on the back of the negative. Twenty years ago the same process was adopted, and the back of the negative was smoked, the drawing made, and from that a duplicate negative. An artist may succeed with such means, but generally this process is not advisable.

### THE HANGING AND ARRANGEMENT OF PICTURES.

THE importance of the tasteful display of photographs in a reception room will earn for the following hints from the "Photo Era" a careful reading:—

The hanging of a picture makes or mars its success as a decoration for the room. If the colours are printed or painted in bright tones, the degree of light needed is not so great, in the daytime or evening, as with colours of less intense hue. Dark corners of the room may be perceptibly brightened by the introduction of pictures in vivid colours—pinks, reds, and yellows.

Large pictures require distance to appear to their best advantage. This rule applies also to compositions of a certain character—winding roads and curving brooks that seem to disappear beyond the horizon.

Family portraits bear so intimate a relation to the life of the household that they belong to the living-rooms, except when for some reason they fit into the scheme of decoration for the formal rooms, hall, or drawing-room.

Portraits of celebrated authors acquire increased interest when placed near their works, and pictures of composers are more attractive when hung near musical instruments. In one library a little gallery of authors' faces was made by filling the entire wall above the book-shelves with prints framed uniformly. The idea might be taken up in a music-room with the same success, using good photographs or engravings of persons eminent in the musical world.

Small pictures distributed at intervals upon a wall lack the style that they give when grouped more closely together. The same principle is true of the small plaster medallions that are usually hung, each by itself, about a room.

Two different methods of hanging pictures with a wire cord can be followed. One is to use one hook for each picture and have the cord form an acute angle where it falls over the hook. The other plan is to use two hooks and two separate cords, the cords making two separate perpendicular lines from picture to hook. The latter way is better for large, heavy pictures, the former more suited to pictures light in weight.

The proper height at which to hang a picture is often questioned. A good general rule is to bring the centre of the picture within eye range of person of ordinary height when standing before it, but this need not be inflexibly followed. Sometimes three pictures framed alike and similar in composition or colouring are to be hung one above the other. The middle picture, which will look better if a size smaller than the other two, should be the one in eye

range, and the space of an inch left between the pictures above and below.

One common mistake of an inexperienced picture hanger is to bring into juxtaposition pictures with dark and light mats. Harmonious results are impossible to effect when this is done.

In many houses the hall-way is quite overlooked in the matter of picture decoration. The opportunity, either in a living or reception hall, is too good to be lost.

#### THE FIRST PORTRAIT BY DAGUERRE.

It will be remembered that in our issue of December 7, 1906, we quoted a letter from Mr. W. Gardner to the "Westminster Gazette," stating that the writer's uncle, an engineer of the past generation, was the first sitter to Daguerre, and that he, indeed, suggested portraiture to Daguerre, who until then had confined himself to turning his camera upon inanimate objects. By courtesy of Mr. Gardner's mother, in whose possession the Daguerreotype now is, we have had a copy made of the portrait. The inscription made by Mrs. Gardner on the back of the portrait, in 1904, runs as follows:—

"This Daguerreotype was given to me by my brother, Andrew Shanks, in 1843. Daguerre had then taken only buildings and land-

Andrew Shanks.

Copy of the Daguerreotype by Bennett Clarke, Wolverhampton.

scapes. At my brother's suggestion he offered to take him, so that this was the first likeness he ever took."

In the absence of documentary evidence of the time it is difficult to verify or disprove the claim of this Daguerreotype to be the first portrait ever made by Daguerre. We have searched in the early literature of the Daguerreotype process for some reference to Mr. Shanks which would fix the date of his conversation with Daguerre, but without success. Although the portrait did not come into the possession of its present owner until 1843 it must have been taken before then if it were the earliest made by Daguerre, because Daguerre, with those who had learnt the process, were making daily use of the process within six months of its being published in 1839.

There is no mention of the incident in Daguerre's "Historique et Invention," published in 1839, but then Daguerre was not in the habit of going out of his way to acknowledge other people's suggestions. The fact that in his directions for exposure he says nothing about portraits leads colour to the supposition that at the time of publication of the book he had not thought of applying his process in this direction. It is possible that the daily and weekly newspapers in Paris for the years 1839 and 1840 might contain some reference to the occasion on which Mr. Shanks' portrait was obtained. So far as we

are aware, it is quite in accordance with the known facts that the art of photographing portraiture might have been practised for the first time on Mr. Shanks' person.

#### PHOTOGRAPHIC SURVEY OF SUSSEX.

The following is the report for the year ending December 31, 1906. In the report for 1905 reference was made to negotiations being in progress for placing the survey on a broader basis and making the collection accessible to all interested in the work. With this view steps taken during the past year have resulted in the transfer of the Public Library, Church Street, Brighton, of the photographic negatives, lantern slides, etc., contributed to the survey; this collection is now in process of being arranged and catalogued. It will be stored in the Reference Library (which is open to the public week-days from 10 a.m. to 6 p.m.), and will shortly be available for inspection by all interested in the survey, as well as by the general public. In the meantime, those wishing to refer to the collection will receive every facility for doing so on application to the Hon. Curator at the Brighton Public Library. Photographs now total 747, negatives about 1,100, and lantern slides 300.

As it is desirable that the working of the photographic survey should proceed from one centre as much as possible, Mr. H. J. Roberts, the Chief Librarian of the Brighton Library, has been appointed Honorary Curator, and Mr. L. A. Gilbert, Honorary Secretary. Their addresses will be: The Public Library, Brighton. Mr. J. C. Stenning will retain the post of honorary treasurer, and proposes to visit Brighton from time to time to help where needed.

An endeavour will be made shortly to organise a systematic photographic survey of the county. Whilst this is pending it is hoped that no opportunity will be lost of rendering assistance to the survey by photographing objects of interest and sending the results to the hon. secretary at the Brighton Library; in exceptional circumstances where no photographer is available, the hon. treasurer would be glad to be communicated with.

The hon. treasurer also desires again to draw the attention of all who possess old photographic or scrap albums, old negatives, or photographs of buildings or of other antiquities in the county to the service that can be rendered to the photographic survey by the lending them for the purpose of copying; any such articles sent to the hon. treasurer will be copied and carefully returned.

The balance sheet shows a total collection of £11 ls. 1d., an increase of more than £3 over last year, whilst the expenditure has been £7 ls. 11d., leaving a balance of £3 19s. 2d.

The annual meeting of the survey will take place on March 12 at the Public Library, Church Street, Brighton.

**FANCY DRESS BALL.**—The employees of Mr. J. F. Lessels, photographers, Aberdeen, were entertained by their principal at the annual fancy dress ball in the West End Café last Friday. The assistants from the studios at Glasgow, Edinburgh, Leith, Dundee, and the various branches in the city assembled, with a few friends to the number of 50, and spent a most enjoyable evening. The host, as Hamlet, looked and acted the melancholy Dane to perfection notwithstanding that the gaiety of the scene did not lend itself to the characteristic gravity of the prince. Miss Lessels, who admirably fulfilled the functions of hostess, was attired as Empress, and looked sufficiently imperial in the part. The other dancers represented a variety of fancy and historical characters, including among the ladies:—French fisher girls, Dutch peasants, Spanish dancers, Summer, Puritan, Ireland, Queen of Diamonds, Japanese, Veronique, Queen of Roses, Marie Antoinette, Snowball, Alice in Wonderland, Colleen Bawn, Hypatia, Vivandière, etc. The gentlemen appeared as naval and military officers, Indian Rajah, Chinamen, Davy Garrick, Beau Brummel, Chief, Weary Willie, Robin Hood, Count Little Pickle, Rajah Bhong, Policemen, Jockey, Chinese Mandarin, Colonials, Cowboys, Toreador, etc. During an interval a very interesting function took place, Mr. Bannerman, on behalf of the employees, presenting Mr. Lessels with a handsome violoncello. Mr. Lessels, in a neat speech, returned thanks for the gift, and hoped that the friendly relations existing between his assistants and himself would long continue.

## Exhibitions.

### NORWICH PHOTOGRAPHIC SOCIETY.

The Norwich and District Photographic Society has now attained to its fourth exhibition, which was opened by the Mayor on February 28, in the Lecture Hall of the Church of England Young Men's Society. It embraces all the usual features and something more; and to the practical photographer it is of the utmost educational value. A considerable proportion of the total exhibits is shown in the highly contested open class, and there is shown, besides a large loan collection of portraiture done by Herr R. Dührkoop, of Hamburg. The Dührkoop pictures (writes the "Eastern Daily Press"), which are lent by the Editor of the *BRITISH JOURNAL OF PHOTOGRAPHY*, and have been seen before on various photographic occasions in other parts of the kingdom, are some seventy-six in number, and they manifest an astonishing variety of manner and tone. Whether the tone be high or low—and it ranges from one extreme to the other—the technical quality is always admirable. There is an absence of pose and an air of spontaneity about all the figures, some of which are taken under conditions of obvious difficulty. Whatever else he ignores, the visitor must see the Dührkoop pictures.

The classification of the competitive photographs, of which there are 424 altogether, has this year undergone an important change. There used to be separate categories, relating to landscape, portraiture and architecture, which are now all merged together in a large open class—Class I. The second class is made up of lantern slides and is open. The third class is free from any limitation in respect of subject, but is restricted to photographers living in East Anglia. The remaining six classes, which relate to landscape, portraiture, architecture, and still life, are limited to members only. In point of average quality the line to be drawn between the members' own exhibits and the exhibits in the open classes is not nearly so marked as it was in previous years. In the competitive departments of the show there is nothing which will attract the attention of the visitor perhaps so strongly as the still life exhibits of Mr. H. J. Comley, of Stroud, Gloucestershire, who has achieved some remarkable effects in colour photography.

The committee are to be congratulated heartily on their arrangements. The competitive work, as shown on two well-displayed screens running lengthwise of the hall, and most of the loan pictures are shown upon the walls at the side. The award list in the open classes is as follows:—

Open Classes.—Class I: Plaque, No. 5, Aubrey Harris; No. 34, John Walton; No. 54, W. J. Clutterbuck; No. 82, A. W. Walburn; No. 14, F. A. Tinker; No. 50, J. J. Rutherford; No. 62, Miss H. Stevenson; No. 4, H. Y. Summons; extra plaque, No. 20, H. J. Comley. Class 2: Plaque, No. 90, A. G. Thistleton; No. 96, J. Ludlam.

### SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The eighteenth annual exhibition of this society was opened on the 2nd inst., and whilst the general average of the work in the members' classes was equally as good as in previous years, there was distinct falling off in the architectural and excursion picture classes. The latter one can understand, but the former is a little curious, considering the very high reputation which the members of this society have held in the past for architectural work. One may almost presume that the members are turning their attention to other classes of work, and, for example, flower studies, of which some fine examples are shown, particularly by the lady members, who deservedly score.

The judges, Messrs. Furley Lewis, J. C. S. Mummery, and E. J. Wall, made the following awards:—

Members' Classes.—A: Portraiture, animals, flowers, fruit, etc. Bronze plaques: "It Is Not Always May," Mrs. K. Whiles; "Madam Carl Droski," Miss M. A. Smart. Hon. mention: "The Little Window," A. E. Bixby. Class B.—Architecture.—Bronze plaque: "Touched with Sunlight," G. J. T. Walford. Class C.—Landscape, seascape, etc. Bronze plaques: "December Sunshine," J. J. T. Walford; "At Bosham," T. Moyser; "Winter," Gideon Mark. Hon. mention: "The Mill," W. Llewellyn White; "Sunshine

and Wind," E. W. Taylor. Class D.—Excursion pictures.—Hon. mention: J. T. French. Class E.—Lantern slides.—Bronze plaques: G. J. T. Walford. Hon. mention: E. C. Seare and J. T. French. Class F.—Champion class.—Gold medal: E. W. Taylor.

Open Classes.—Class H: Portraiture, etc.—Silver plaque: "Portrait of Cecil Heywood," E. O. Hoppé. Bronze plaque: "Japanese Pæonies," Miss L. Marillier; "A Portrait Group," Oscar Hardee. Hon. mention: "The Nation's Pictures," E. T. Holding; "Oranges and Nuts," H. Comley; "Fairy Tales," C. A. Morgan. Class J.—Architecture.—Silver plaque: "A Play of Sunlight," J. W. Johnson. Bronze plaque: "A Norman Triforium," G. J. T. Walford. Class K.—Landscape and seascape.—Silver plaques: "Bruges Canal," Oscar Hardee; "Trafalgar Square," F. Warner. Bronze plaques: "The Medway at Rochester," A. H. Piddington; "The Pathway," R. G. Cripple. Hon. mention: "The Garden of Allah," L. J. Steele; "Off to the Fishing Grounds," G. J. Rattle. Class L.—Lantern slides.—Silver plaque: E. R. Bull. Bronze plaque: G. J. T. Walford and A. G. Thistleton. Hon. mention: Ellis Kelsey and G. A. Booth. Class M.—Stereoscopic.—Silver and bronze plaques: H. Wormleighton.

The bronze medal in the Edwards' Memorial Competition for the best monochrome reproduction of a coloured picture was awarded to Miss M. A. Smart.

For the best novelty in the trade section the medal was awarded to Messrs. Watson and Sons' new Holo convertible wide angle lens; and that for the best stall to Messrs. Prosser, Roberts, and Co.

### WORTHING CAMERA CLUB.

OWING to the great success of the Worthing Exhibition last year the committee endeavoured to make still more extensive arrangements, and this year's show, which was held on the four last days of February, was again a very great success. Entries in the open class had almost doubled themselves, 149 frames being hung. Amongst these the three-colour carbon work of Mr. Henry J. Comley, who secured the premier award (silver plaque) stood out prominently. Mr. Comley's print was purchased by the club for their permanent collection. The work of the members showed a decided advance on pictorial quality, and was well above the average seen at provincial exhibitions.

The lantern slides, too, were worthy of mention. Besides those which were shown daily, there was an excellent programme of lectures.

Messrs. A. Horsley Hinton and Oliver G. Pike undertook the judging, and the following is their list of awards in the open classes:

Class A.—Silver plaque: "A Corner of the Larder," Henry J. Comley. Bronze plaques: "The Rescue," Ellis Kelsey; "Grey Morn," James C. Batkin; "Barn Owl" (from life), Alfred Taylor; "Low Tide," Walter Selfe. Hon. mention: "Gooseberries," Robert Burnie; "Home of the Crested Grebe," W. Farren.

Class B.—Bronze plaques: "Evening," W. Selfe; "Song Thrush," G. A. Boothe. Hon. mention: J. Easonsmith and R. Burnie.

### FORTHCOMING EXHIBITIONS.

1907.

March 2 to 24: Marseilles Photographic Society.—Sec., M. Cullet, Rue St. Savournin, 38, Marseilles.

March 7 to 16: Leicester and Leicestershire Photographic Society. Entries close February 16.—Sec., Lewis Ough, "Fernleigh," St. James' Road, Leicester.

March 12 to 13.—G.E.R. Mechanics' Institute, Stratford (photographic section). Entries close March 2. Sec., A. Woolford, 16, Grove Green Road, Leytonstone, N.E.

March 14 to 16: Coventry Photographic Club. Entries close March 9.—Sec., T. J. Mercer, 6, Cope Street, Coventry.

March 22 to April 13: Northern Photographic Exhibition. Entries close March 8.—Sec., C. F. Inston, 25, South John Street, Liverpool.

March 23 to April 2.—Glasgow Southern Photographic Association. Entries close March 16.—Sec., Charles Young, 217, Crow Road, Partick, Glasgow.

April 10 to 13: Ilkeston Arts Club, Photographic Section. Entries close March 27.—Sec., A. Smith, 11, Graham Street, Ilkeston.

April 17 to 19: Belfast Y.M.C.A.—Sec., J. W. Bushey, Y.M.C.A. Camera Club, Belfast.

April 25 to 27: Wallasey Amateur Photographic Society. Entries close April 10.—Sec., W. Hayes, 110, Brighton Street, Seacombe.

April 29 to May 14: Photographic Society of Ireland. Entries close April 22.—Sec., R. Benson, 35, Molesworth Street, Dublin.

May 6 to 10: Chemists' Trades.—Sec., A. Norman Flack, "British and Colonial Druggist" Offices, 44, Bishopsgate Street Without, London, E.C.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following Patents were applied for between February 18 and February 23:—

**SHUTTERS.**—No. 4,024. Improvements relating to shutters for photographic apparatus. Wilhelm Kengott, 111, Hatton Garden, London, E.C.

**CINEMATOGRAPHS.**—No. 4,168. Improvements in lens mechanism for cinematograph apparatus. Robert Thorn Haines, 322, High Holborn, London, W.C.

**CAMERAS.**—No. 4,351. Improvements in photographic cameras. Arthur Lewis Adams, 26, Charing Cross Road, London, W.C.

**RELIEFS.**—No. 4,361. Method of producing bas-reliefs for decorative purposes and for the production of photographs and printed matter, with relief-like effects. Rudolfo Namias, 40, Chancery Lane, London, W.C.

**DEVELOPING APPARATUS.**—No. 4,386. Improved photographic dark-slide or light-trapped case for exposing, developing, and fixing flat films or plates in daylight. Charles Johnson, Birkbeck Bank Chambers, Holborn, London, W.C.

**DEVELOPING APPARATUS.**—No. 4,526. Improvements in photographic developing apparatus. Eugen Bader, 7, Southampton Buildings, London, E.C.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**CAMERAS.**—No. 12,254. 1906. The invention consists of a roll film camera, in the back of which is an aperture through which notes and memoranda may be made on the paper cover of the film. The aperture is provided with a shutter. The author says: "As it would, however, be difficult to make a record on the black paper, I use the film with unsensitised strips at intervals along its length, on which the notes are made through an aperture in the black paper corresponding in size to that of the aperture in the back of the camera, but I make no exclusive claim to such films. Instead of using films having unsensitised strips at intervals I may employ films fully sensitised, but of extra lengths, to provide spaces for recording the notes, but to such films I make no claim." Joseph Constance Jones, 20, Walsingham Road, Hove, Sussex.

**PLATE-HOLDERS.**—No. 5,212. 1906. The invention relates to camera slides and plate-holders of the kind referred to in Patent Specification, No. 7,757, 1899.

As shown by the sectional drawing, the plate carrier or holder A, is composed, as usual, of a sheet of metal, celluloid, stiff paper, or other thin material having its two sides a bent or turned over to form side grooves into which the sensitive plate or film fits, and one end closed by a cross bar b, while the other end, which is not turned over but is open to admit the plate, is entered into

an outer carrier A<sup>1</sup>, whose two sides, a<sup>1</sup> and inner end b<sup>1</sup>, are bent or turned over to form grooves, in which the inner plate holder A may slide.

A sliding flap or shutter C is entered into hollow grooves formed by the spaces between the turned over edges a and a<sup>1</sup> of the inner and outer carriers A A<sup>1</sup>.

The inner end of this shutter C enters a groove formed between the turned over edges b<sup>1</sup> of the outer carrier, and a cross bar a<sup>2</sup> of wood or the like, against which the end of the inner holder A abuts. A cross bar c, secured to the outer end of the shutter, is provided for drawing it out of the carrier A A<sup>1</sup>, and to close up the open outer end of the latter so as to exclude

light, the said cross bar c, bearing for that purpose on a velvet or like pad, d, as is usual, at the outer end of the inner carrier or plate holder A, while the turned over edges a of the latter and the cross bar b at the inner end of the outer carrier A<sup>1</sup>, serve to exclude stray light from the remaining edges of the plate. Frederick MacKenzie and George Wishart, 17, Douglas Street, Glasgow.

**SHUTTERS.**—No. 2,713. 1906. The invention consists of a diaphragmatic shutter, including a number of aperture plates, an air and escapement mechanism. The description entails reference to the seven detailed drawings in the specification. Gustav Dietz, 20, West 31st Street, New York, United States.

**CAMERAS.**—No. 20,142. 1906. The invention is in reference to cameras, in which the front is pivoted to the baseboard and automatically comes into vertical position when the camera is opened. A group of levers is provided on either side of the front, so that when the front is raised by means of a suitably mounted tie rod, a lever (4) is turned by striking against a fixed stop, in such a manner that a second double-armed lever moved by it holds the front in vertical position.

The tie rod 1 is at one end pivoted to the camera casing, and at the other end hinged to the lever 3 on the camera front, rotatably connected at 2 to the baseboard. On the pivot point 2

is pivoted a second lever 4, provided at the top with a lug or fork 5, and at the bottom with a pin 7 engaging in a slot 6 in the lever 3. When the tie rod 1 is left behind during the opening of the camera, the said pin 7 rests against the foot 8 secured to the folding baseboard, so that the lever 4 has to turn about 2.

The fork 5 is in engagement with a branch of a lever 9, which is pivoted at 10 to the lever 3. The other end of the said lever 9 forms a projection which, on the camera being opened, presses

a pin 12 secured to the front board 11, into a notch 13 in the lever 3, and thus holds it fast.

When the apparatus is opened, the tie rod 1 pulls the lever 3 on the front into vertical position. The front board 11 hinged at 14 is brought forward, and the pin 12 engages in front of the notch 13. At the same time, owing to the pin 7 striking the foot 8, the lever 4 is turned about its pivot point 2, and thus the lever 9 is turned about its fulcrum, so that it engages with the upper arm behind the pin 12 and holds it in the notch 13. A. J. Boulton, for the Fabrik Photographischer Apparate auf Aktien vormals R. Hüttig and Sohn, 76, Schandauerstrasse, Dresden, Germany.

The following complete specification is open to public inspection for acceptance under the Patents Act, 1901:—

**SHUTTERS.**—No. 4,024. Shutters for photographic apparatus. Wilhelm Kengott, 111, Hatton Garden, London, E.C.

### New Trade Names.

**INKA.**—No. 289,850. Chemical substance used in manufactures, photography, or philosophical research, or anti-corrosives. Kirchhoff and Neirath, 23, Oranienburgerstrasse, Berlin, N., Germany. Manufacturing chemists and novelty vendors. January 2, 1907.

### Analecta.

*Extracts from our English weekly and monthly contemporaries.*

#### The Boon of Telephoto Anachromatism.

Mr. Will. A. Cadby, writing in the "Amateur Photographer," on the "Adjustable Landscape Lens" of M. Morin, says:—

"It is an immense advantage in a landscape lens to have it adjustable, by which I mean the power to alter the size of the picture without moving the position of the camera. If we want our subject large, we extend the bellows, and focus accurately with the rack and pinion attached to the lens, exactly in the same way as with the Adon's telephoto when used alone. Indeed, size is only limited by the length of bellows attached to our camera, within, of course, reasonable limits. A very little reflection is needed to enable us to realise the advantage of this arrangement, for the one instrument forms in itself a whole battery of lenses, and the picture can be taken the exact size wished for without dodging backwards and forwards with the camera.

"To sum up, it seems to me that this lens might form the turning point in many a wavering photographic career. The disappointed worker, at the end of his tether, sick to death of his sharp, all-over-licious of indiscriminate landscape, will find it a means to make his nature prints at least more attractive and less obvious, for it lends quite pleasing quality to the most ordinary view. The lens, at all events, will do its part of the work artistically, and this is saying a great deal."

#### Coloured Miniatures on Bromide Opals.

Writing in "Focus" of March 6 on the preparation of miniatures made on bromide opals and coloured with dry powder colours, such as Barnard's "Velvotints," the Rev. Canon Day gives the following description of the fixing process which must be used to soften the coarse effect obtained by the first application of the colours:—"All this is remedied by the subsequent process, which is the secret to the beautiful delicacy seen in miniatures, produced by this means. After dusting off any superfluous colour, the opal should be held, at a distance of 12 inches, from the spout of a kettle, the water in which has been made to boil briskly. This allows a good spray of steam to spread over the surface of the picture, and has the effect of fixing the colours and refining and blending them at the same time; of course, if the opal is held too close, or for too long a time in the steam, the heat will melt the gelatine basis of the picture, and the work be ruined irretrievably. Five seconds in a good volume of steam will be quite sufficient to fix the tints, without allowing moisture to condense upon the film."

### New Books.

"British Birds' Nests." By Richard Kearton, F.Z.S. 520 pages, 9 x 6. London: Cassell and Co., Ltd. 21s.

This handsome volume is the outcome, so the author tells us in the preface, of a resolve made fifteen years ago to write a book on British birds' nests, and to illustrate it from beginning to end with photographs which should "show things as they are, and not as they are supposed to be." Mr. Kearton, with the assistance of his photographer-brother, has had the thanks of the public for quite a number of books since that time, all presenting various aspects of bird and insect life in a way which fascinated the reader, while it left him marvelling at the prodigious patience which the photographic illustrations implied. Yet probably none of the previous works of the Kearton Brothers partake of the character of the present one, which is not a narrative, but a book of reference, and is, in fact, arranged dictionary fashion, with the items in alphabetical order from "Accentor" to "Yellow hammer." But the term "dictionary" should not mislead the reader of these lines, for the volume is more like a picture-book than anything else, from the inclusion, with scarcely an exception, of a photograph of each bird's nest, and in many cases of the bird in its natural haunts.

The information given under each heading comprises a description of the parent birds, and of the situation and locality of the nest, a description of the eggs, and notes on the time at which the birds are sitting. In addition to the numerous half-tone illustrations in the text there are six photogravure plates and sixteen three-colour reproductions of eggs.

"Les Positifs sur Verre." By H. Fourtier. 188 pages. 7½ x 4½. 3fr. 75c.

"Les Projections Scientifiques et Amusantes." By G. Massiott. 48 pages. 9 x 5½. 1fr. 75c.

"Conseils aux Amateurs." By Maurice Mercier. 144 pages. 7½ x 4½. 2fr. 75c.

Of these three volumes, from the publishing house of M. Gautier-Villars, Paris, the first two deal with lantern matters. M. Fourtier's treatise treats of the processes of slide making, including the preparation of stereoscopic transparencies. It gives instruction in the collodion and albumen processes, as well as the use of the more popular bromide and gaslight gelatine plates.

The second brochure describes about twenty experiments of an instructive or entertaining character, which can be shown on the screen with a modern projection lantern. A number of the devices in which a physical phenomenon is presented to the spectator in a novel and spectacular manner are highly ingenious, and the little book should be of service to science lecturers employing a lantern, not merely for its actual instructions, but for its suggestion of means to make scientific instruction entertaining at the same time.

M. Mercier, a lively writer, well describes his book as "Conseils," for the latter is not a systematic text-book, but a series of papers chiefly on negative making, in the course of which the author manages to convey a good deal of information in a bright conversational way. Some of his recommendations, for example, picric acid in the developer, are unusual; but he is evidently writing out of his own experience.

"Wagner's Lohengrin." Retold in English and illustrated in colour by F. C. Tilney. 95 pages, 8 x 5. London: George Routledge and Sons, Ltd. 3s. 6d.

Bravely does Mr. Tilney attack the mystical German romance, and, reducing it to its elements, remould the story nearer to the comprehension of the boys and girls in their teens—for whom this elegantly produced volume is doubtless intended. It is no easy task to present the story of Lohengrin in a way which is comparable with Lamb's tales from Shakespeare, but Mr. Tilney manages to interest us in the trial of Elsa and her rescue by the mysterious knight. The volume contains half a dozen reproductions in three-colour of the author's paintings illustrating the story, and is alto-

gether a delightful gift-book to place in the hands of anyone with a taste for the legends on which Wagner founded his operas.

"THE PRACTICAL AND PICTORIAL PHOTOGRAPHER" has changed its character to some extent on passing into the hands of new proprietors, Messrs. Robert Atkinson (London), Ltd., 10, Essex Street, Strand, W.C. One notable innovation which we see for the first time in the March issue just published is the use of a matt paper for the half-tone plates. The illustrations lose very little in detail, and the general effect from the artistic standpoint is immeasurably superior to that on art paper. Among the literary contents are contributions from Mr. Chapman Jones, Horace Mummery, and T. Thorne Baker, and a symposium on refinements of bromide printing.

## Dew Apparatus, &c.

Thornton-Pickard Cameras, 1907 Models. Made by the Thornton-Pickard Manufacturing Company, Altrincham, Cheshire.

Almost exactly a year ago we reviewed several new cameras which the Thornton-Pickard Company were then adding to their series. We have now to pass judgment upon the latest model of the oldest camera of their manufacture, originally the "Ruby," but now, in its perfected form, the "Royal Ruby." It represents the firm's supreme achievement in camera construction, and a truly remarkable achievement it is.

Vertical swing to front and back. Also showing short focus movement at front of camera, without protruding baseboard.

The improvements which mark the camera out from previous models lie chiefly in the lens front. The latter is now attached to the front of the baseboard by a system of levers, and has not, as previously, to be set in place by the user when opening the camera. Instead, the act of drawing out the bellows brings the front into exact perpendicularity with the baseboard and locks it there. Similarly, the back is automatically locked square with the baseboard; so that the camera is adjusted, at once and independently of the operator's judgment, in the position in which it is required to be for the great majority of work.

To return to the front. The levers which support it permit of the front being made wider and higher, apparently a small matter, yet, in fact, the key to the improvements in the camera. The larger front allows a bellows of slightly less tapered shape, and, as a result, the positions of wide angle combined with rise and fall, which the camera can assume are incredibly advantaged under the new construction. The double-lever support of the front likewise gives a very rigid position of the latter, and permits of the front being held out beyond the baseboard, an addition to the camera's already very ample provisions for extension. Similarly the front is projected towards the focussing screen, where it is adjustable up, and down, and where also, as in all other positions, it can be swung

through an angle which is only limited by its juxtaposition to other parts of the camera.

We confess that the task of lucidly setting forth the facilities which are thus provided is no light one, and may also lead us to overlook the extra movements of rise and fall by the system of divided panels, the scientific balance of the whole apparatus at its extension of 25 inches (half-plate) and of other minor matters, which nevertheless contribute to the efficient use of this camera—e.g., the new pinion to the lens front, which both controls the rise or fall and clamps the front firm. The illustrations of the camera in different

Rising front with independent rising panel. Total rise above centre 3½ in.

positions, but not extreme ones, will better convey an adequate idea of the range of movements of this handsome instrument. The half-plate size is an ideal tourist's field camera, and the larger sizes are equally effective in the hands of photographers called upon to undertake technical work of the most difficult kinds. And the last word must be one of surprise that, with all the added improvements, this company should have been able to reduce prices. This they have done to an appreciable extent. The half-plate set, with R.R. lens, three-fold tripod, T. and I. shutter, and one dark slide, now costs £10 10s.

Fall over front of baseboard. Universal swing front in action.

The 70s. half-plate set of the Thornton-Pickard Company, which must be next mentioned, has been still further improved for the coming season in a number of details which make for comfort and speed in working and enhance the already extraordinary value which is offered at the moderate figure of £3 10s. All the brass work is now made with rounded corners, the reversing back faster in place with spring snaps instead of the previous hook clips, and the dark slide is automatically secured by a spring clip instead of turn button, minor additions which any worker will be thankful for. The upright struts (now brass) of the lens front are made to splat

outwards, the camera thereby closing more easily, owing to the struts assisting the compression of the bellows. Previously these struts were of wood, but the change to metal has made possible a wider lens panel and a better range of movements. As it now stands, the "Imperial Triple Extension," as the 70s. set is called, is perfectly adapted for a very wide range of work.

"Duo" Anastigmat Lenses. Made by Aldis Bros., Old Grange Road, Sparkhill, Birmingham.

A step forward in lens construction has been made by Messrs. Aldis, the announcement of which should be received with a good deal of interest by the many users of their anastigmat, as well as by those who at the moment may be halting between many opinions as to which lens to select as an addition to their equipment. The Aldis anastigmat, we may say for the information of those who do not possess it, differs from the majority of instruments in not being separable into two separate lenses. It is of the simple construction which permits of great optical perfection of the lens as a whole, yet does not allow of the division of the lens into two working parts. That fact is largely discounted by the fact that a purchaser might obtain two complete Aldis anastigmats, of the foci he would require, for little more than the money he would pay for a divisible lens, and at the same time he would get the longer focus of the same rapidity as the smaller. Yet the same, or lesser, facilities in one lens only are probably preferred by the majority of tourist photographers, and it will therefore be a satisfaction to them that the new "Duo" system gives them the choice of foci without the drawbacks of two separate complete lenses.

In short, Messrs. Aldis have perfected a small lens element, which replaces the front combination of the anastigmat and converts the latter into an anastigmat of double the focal length. We have had an opportunity of putting the new system to the test of trials extending over a considerable time. The particular "Duo" that we have tested is intended for use with the No. 7 Series III.  $f/7.7$  anastigmat of  $7\frac{1}{2}$  inches focal length. When substituted for the original front combination an anastigmat of 15 inches focal length and effective aperture of about  $f/17.5$  is produced. This 15-inch doublet seems to be a remarkably well corrected instrument, and it gives perfect definition with full aperture over a half-plate with scarcely a sign of astigmatism. Stopped down, it will, of course, cover a larger plate, but as the original No. 7 lens is essentially a half-plate lens it is probable that this "Duo" combination will be mainly used with half-plate cameras. Fifteen inches is a most useful focal length for half-plate work, but a 15-inch anastigmat is usually very expensive. The "Duo" should easily become popular, as its combined

qualities of smallness, cheapness, and high quality will be hard to beat, and for all classes of work it is a lens which we should have no hesitation in recommending to a photographer requiring a high standard of excellence in his negatives. The drawing shows (on the right-hand side) the full size and construction of the No. 7 "Duo" front element in conjunction with the back element of the Aldis anastigmat.

## Photo-Mechanical Notes.

The following patents have been applied for:—

PHOTO-MECHANICAL PRINTING.—No. 3,363. Improvement in photo-mechanical printing. John William Ippers, 65, Chancery Lane, London.

PRINTING-PLATES.—No. 3,538. Improvements in the production of plates for printing purposes. Sherard, Osborn Cowper-Cowles, 4, South Street, Finsbury, London, E.C.

## New Materials.

Cream-Crayon "Zigo" Self-toning P.O.P. Made by Thomas Illingworth and Co., Willesden Junction, London, N.W.

Those who want an effect very similar to the toned bromide, but obtained simply by printing-out and fixing, should give Messrs. Illingworth's new variety of "Zigo" a trial. The tint of the paper harmonises well with the colour of the image, and the whole effect is of a kind to satisfy the worker who is discontented with the gloss or semi-gloss of P.O.P. Like the other brands of "Zigo" paper, glossy and matt, the operations following printing are limited to fixation for about six minutes in a hypo bath and washing for the usual time. The "Cream-Crayon" is supplied in sizes and at prices uniform with those of the existing papers and based on 1s. for the packet of 25 quarter-plate pieces, or 1s. 11d. for two sheets,  $24\frac{1}{2} \times 17$ .

PICTURE POSTCARDS.—The London Studio, 20-22, St. Bride Street, Ludgate Circus, E.C., send for our inspection a number of specimens of pictorial postcards in half-tone, which they prepare from photographers' originals, they making and printing the blocks at prices which are announced elsewhere in this issue. The cards before us are excellent examples of half-tone.

LETTERING PRINTS AT THE TIME OF EXPOSURE.—A sample of the useful outfit supplied by him is submitted to us by Mr. G. H. Eustace, Grimsby. The method calls for no special skill in use, and is one which should be of service to photographers issuing postcards.

REVISED PRICES of the Ilford "Amauto" self-developing plate appear in the current issue of "Photographic Scraps" as follows:—

	Per doz.		Per doz.
$3\frac{1}{2} \times 2\frac{1}{2}$ .....	1s. 0d.	$5 \times 4$ .....	2s. 6d.
$\frac{1}{4}$ -plate .....	1s. 6d.	$\frac{1}{2}$ -plate .....	3s. 8d.
$5\frac{1}{2} \times 3\frac{1}{2}$ .....	2s. 6d.	1-1 plate .....	7s. 6d.

## CATALOGUES AND TRADE NOTICES

THE PHOTOGRAPHIC CATALOGUE of the British Dispensary, New Road, Bangkok, the largest source of supplies in Siam, reaches us from the proprietors. It is satisfactory to note that the goods are almost entirely supplied by British houses.

"THE PROFESSIONAL PHOTOGRAPHER."—No. 4 of this publication of the Kodak Company contains some interesting notes on Mr. Drummond Shiels, of Edinburgh. There are a number of excellent half-tone reproductions of portraits.

LISTS OF THE STOCKTAKING SALE now in progress at Messrs. Houghtons, 88-89, High Holborn, are now obtainable, and describe a great variety of mounts, cameras, lenses, and camera cases offered at large reductions of the regular prices. Messrs. Houghtons also send us a booklet illustrating the styles of catalogue which they can offer to suburban and provincial dealers, with his (the dealer's) address and other announcements added on the covers. The booklet should repay the attention of dealers not in a position to issue lists entirely of their own.

THE ANTHONY AND SCOVILL COMPANY, Binghampton, New York, U.S.A., send us their catalogue of supplies for photographers and photo-engravers. It at once impresses a British reader from the fact that not a single woodcut appears among its illustrations. Half-tone photographs or wash-drawings of the apparatus are exclusively used, and the list thereby gains in effect. The American buyer, too, is not offered the endless variety of accessories and attachments which he can see described in the dealers' lists here, and apparently he is none the worse off.

LAFAYETTE, LIMITED, DUBLIN.—The directors' report to the shareholders, submitted last week, showed that the net profit made during the year was £7,000. Dividends of 6 per cent. on the preference and of 10 per cent. on the ordinary share capital of the company were ordered to be paid to the shareholders.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### FRIDAY, MARCH 8.

Sutton Photographic Club. "Photographic Failures and their Remedies." Oliver Goldsmith Photographic Society. "Theory and Practice of Softening Papers." John Griffin & Sons.  
Cardiff Photographic Society. "Photography by Artificial Light." W. J. Jenkins.  
Hamstead Scientific Society. "Wild Traits in Domestic Animals." J. A. Simes.  
Loughton Photographic Society. "Alpine Passes." Geo. Lamley, F.R.P.S.  
Photographic Society of Ireland. "Lectures." By Members.  
Nottingham Camera Club. "Contact Printing on Slow 'Rotograph' Bromide Paper."

#### SATURDAY, MARCH 9.

Edinburgh Photographic Society. "The Pentlands and the Moorfoots: Their Historical Associations and Scenic Beauties." Illustrated. W. Reid.  
Photo Art Club. Outing to Grandholm.

#### MONDAY, MARCH 11.

Preston Camera Club. "Five Minutes' Lectures." By the Members.  
Southampton Camera Club. "Zermatt and Beyond." Part II. Illustrated. W. R. Kay.  
Central Photographic Society. "Fire-Side Chat on Work for Winter Evenings." By H. J. Lewis.  
Gravesend and District Photographic Society. "Rambles in Lakeland." Hurst and Carpenter.  
Oxford Camera Club. Lantern Slide Competition and Exhibition of Members' Work.  
Derby Photographic Society. "1906 Competition Prints." W. R. Bland.  
Blackburn Camera Club. "Flower Photography." H. T. Maiby.

Richmond Camera Club. "Illuminated Manuscripts in the British Museum." H. J. Ellis.  
Handsworth Photographic Society. "Mounting Prints by Various Methods." Messrs. Baker, Cope, and Proctor.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held March 5, Mr. J. C. S. Mummery, president, in the chair. The third of the series of demonstrations of ancient photographic process was given by Mr. A. C. Braham, of the Autotype Company, on "Wet Collodion." After explaining the method which must be adopted in cleaning the glass for a wet collodion negative or transparency, the lecturer proceeded to prepare some collodion by solution of pyroxyline and papyroxyline, in the usual mixture of alcohol and ether. He explained the iodising of the collodion, and named ammonium and cadmium iodides as the salts most frequently employed. The operations of coating, sensitising, and developing were shown, and the lecturer then proceeded to demonstrate the

applicability of the collodion process to the preparation of combination negatives by the stripping of the film from one plate on to another negative. He showed how the process was carried out in the case of a face which it was desired to add to a different body. The stripping was done in a solution of sulphuric acid of strength about 1 in 40 of water.

In the course of the discussion which followed, Mr. Clift referred to the unsuitability of vulcanite for the material of the vessel for the silver bath. It led to the rapid deterioration of the bath. Mr. Clift stated, as the result of seventeen years' experience of the wet collodion process, that the bogey of the silver bath, which was so frequently held up by those who had worked the process, had little existence in fact, provided that the bath was not overworked, and that all the ordinary precautions were taken. He thought that the reputation which the bath had for suddenly and inexplicably going wrong was not merited.

Mr. Oliver S. Dawson said that a chief merit of the wet collodion process was its cheapness. His own estimate of the relative cost of wet collodion process, as compared with dry plates, was that a plate which cost 14d. by wet collodion cost 1s. 6d. by the dry gelatinobromide plate.\*

In the further discussion Messrs. Rapson, Teape, McIntosh, T. E. Freshwater, Haddon, C. E. Donne, and the Rev. F. C. Lambert took part.

CENTRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.—On February 27, a paper on "Photography with Beck Lenses" was read. The paper discussed pictorial and technical methods, the technical points being illustrated with architectural as well as landscape views. A great many of the photographs were taken on 12 x 10 plates with a 1/1 plate lens in order to show the marginal definition that could be obtained. Several diagrams were shown illustrating the flatness of field of various types of lenses.

CROYDON CAMERA CLUB.—Mr. A. M. Arbuthnot last year showed a pigment paper of his own invention based on the "gum" process since when further modifications have been effected, and it is now commercially made, and known as the "Leto Pigment Paper." Although Mr. Arbuthnot contents himself by leaving demonstrations to the firm responsible for its manufacture, yet, being an old friend at Croydon, an exception was made in the Club's favour on the 27th ult. A notice of the paper in question appeared in our last issue, together with some working details, and there is therefore no necessity to recapitulate them here. It will be sufficient to say that one and all expressed their appreciation of the paper, on the ground of its ease of working, and beauty, and certainty of results, combined with control. In reference to the gum-bichromate process, the lecturer stated that generally speaking the worker had to resort to multiple printing, up to eight impressions or more, and the labour involved was great, as only those who went through with it knew. With multiple prints, moreover, there was great danger of getting too heavy a result, and though at times a heavy, low-toned picture was desirable, yet repetition produced monotony. He had consequently some time ago come to the conclusion that the only possible means of getting light, delicate effects, in a medium which would allow of personal expression, was a return to the old single-print "gum," or rather a modified form of it. The main defect of the gum process was its uncertainty, principally due to the tendency of the gum to become acid, and attendant alteration of viscosity. "Granularity" was also a feature of the process as usually worked. In an endeavour to overcome the foregoing troubles, he had experimented with practically every possible variation of colloids, and it was only by striking out in an entirely original direction that he had succeeded in producing the paper before them. The lecturer then proceeded to sensitise several sheets of paper, and to develop exposed prints by means of a spray, the President, Mr. A. E. Isaac, who assisted, getting liberally drenched during the operation. A sporting element attached to the prints, some of which had been printed at the works, others by the lecturer's housemaid. In fairness to the feminine sex, it must be recorded that, judging by results, it fully held its own against the combined talent of the works.

\* An article on this subject in which a very different ratio was arrived at appeared in our issue of Feb. 15, 1906.—Eds. "B. J."

## Commercial & Legal Intelligence.

**CARL HENTSCHEL, LTD.**—The report for July, 1905, to December, 1906, shows that the net profits for this period was £15,556. Various charges, including the preference interim of 6 per cent., and the writing off of preliminary expenses, absorb £9,210, thus leaving a distributable balance of £6,346. This allows a dividend of 8 per cent. on the ordinary shares. The forward balance is £843. The report says that a considerable amount has been expended on improvements in plant, the benefits of which will be reaped this year. Also arrangements have been made to cope with the company's important Paris business by establishing works in the gay city.

**A TROWBRIDGE BANKRUPTCY.**—Edward George Shotter, formerly of Salisbury, and of Frome, and now of 85, Park Street, Trowbridge, appeared last week before the Bristol Official Receiver. The liabilities amounted to £142 1s. 9d., and there was a deficiency £140 1s. 9d. The debtor attributed the chief cause of his failure to loss on stock by fire, which occurred on his premises at Westgate Street, Gloucester, last June. His loss on that occasion was £75. According to the Official Receiver's observations, the debtor, who is 29 years of age, began business in December, 1904, as a photographer, at Winchester, without capital. He had since resided at the following towns:—Gloucester, Frome, Sutton-in-Ashfield, Kirkby-in-Ashfield, Reading, and Trowbridge. Before starting as a photographer he was an insurance agent. His liabilities were all in respect of goods supplied or work done. He attributed his insolvency to the fire which occurred last June. His effects were uninsured, and he estimated that he lost about £250, although the deficiency account only recorded a loss of £75. The only account book kept by the debtor appeared to show his receipts and payments from February to June, 1906. The public meeting takes place at Bath on March 21.

**CHARGED BY HIS FATHER.**—Cecil Ernest Swanland, photographer, of Glenfield Terrace, West Ealing, was charged at the Highgate Petty Sessions with stealing in November last a camera, three lenses, and one burr, together value £50, the property of his father, Alfred Swanland, photographer, of High Street, North Finchley. Prosecutor said prisoner had helped him in his business; in fact, at the time of the alleged offence, he was practically master of it. On November 27 prisoner left the studio on the plea of going to photograph a house, taking the articles in question with him, but never returned. Prisoner, who made no reply to the charge, was again remanded.

**ALLEGED FRAUDS BY A PHOTOGRAPHER'S CANVASSER.**—Edward Jones, aged 30, described as a canvasser, of 90, Kimberley Road, Edmonton, was charged on a warrant, before Mr. Paul Taylor, at Marylebone Police Court, on Tuesday, with obtaining 6s. by false pretences from Margaret Coghlan, with intent to defraud.

The prosecutrix, a domestic servant, in service at 17, Frognal, Hampstead, stated that on February 4 the prisoner called at that address and explained to her that he had started in business for himself as a photographer at 285, Oxford Street. He showed her some coupons, and said he would be opening on February 6. "We are doing a dozen cabinets for 10s. 6d.," he explained, and, pointing to one of the coupons, he said: "This is my coupon, and if you buy this for 3s. you can have a dozen cabinets for 10s. 6d. and pay 6s. 6d. at the studio when sitting." She then left him to get 3s. and her photograph, and when she returned he said: "I will tell you what I will do. If you pay 6s. now you will only have to pay 4s. 6d. when sitting, and I will give you an enlargement with the dozen cabinets if you will allow me to put one in the window." She accordingly paid him 6s., and not until he had gone did she notice that the coupon he had given her was without a signature. Subsequently she went to 285, Oxford Street, and found that she had been defrauded.

The magistrate: In what way?

Witness: Mr. Mallia, the photographer, carrying on business there, told me this man was discharged by him last October, and that he (prisoner) was not in business there for himself. I thought from what the prisoner said that he was Mr. Mallia.

The prisoner remarked that he was allowed to take 3s. for each

half dozen, but the magistrate pointed out that according to the prosecutrix he was discharged from Mr. Mallia's service a long time ago.

Mr. Mallia was then called. The prisoner, he said, was formerly in his service as a canvasser, but had not acted in that capacity since last October.

The prisoner proceeded to cross-examine Mr. Mallia on irrelevant matters, but the magistrate stopped him, remarking that the question was whether he had committed a heartless fraud. Mr. Mallia, added that the prisoner had taken 3s. from servant girls and told them to go and get their photographs taken, and as a result hundreds of servants had come to his premises and completely disorganised his business.

Detective-Sergeant Ballard said there were several other cases that might have been gone into. There were also previous convictions against the prisoner, including one for perjury and fraud on January 13, 1906; another on October 20, 1897, at Ely Quarter Sessions, of nine months for larceny from a dwelling house; and a third on October 3, 1899, at the North London Sessions, of eight months for stealing a cash-box, etc.

Formal proof having been given of the previous conviction of eight months for stealing a cash-box in October, 1899, the prisoner pointed out that he had a five years' character from a certain firm. Sergeant Ballard informed the magistrate that at the time he was applying at that Court for a warrant for the prisoner's arrest, he learned that a warrant had also been applied for against him at Hampstead. The person in that case, however, did not wish to proceed further, in view of the prisoner being arrested on the present charge.

Mr. Sims, from the solicitors' department of the Treasury, who was present in Court in connection with the Whiteley murder case, also identified the prisoner, and communicated the fact to the magistrate.

Mr. Paul Taylor committed the prisoner for trial.

At the Highgate Police Court, also last week, Maurice Jones was charged with obtaining, by means of false pretences, 2s. from Millicent Mitchell, 3, Duke's Avenue, Muswell Hill, and 3s. 6d. from Louie Prince, 11, Westfield Avenue, Muswell Hill. Three further charges of a similar nature were now preferred against him, two relating to persons residing at Granville Place, South Kensington, and the other at Highgate.

Mr. Mallia, 285, Oxford Street, W.C., gave evidence, and prisoner was committed for trial on the three charges, bail being allowed.

### PROFITS ON PICTURE POSTCARDS.

To the Editors.

Gentlemen,—As I stand in a somewhat unique position with regard to postcard publishing, as a professional photographer I should like to say a few words on the subject. I am the only photographer in this town, which has a population of 17,000, and I have a monopoly of the postcard view trade with the stationers and tobacconists. About four years ago when the pictorial postcard craze was beginning to show in this town and district, although late in the season, I did not sit and see others reaping the benefit. I knew that it was "grist" that ought to come to my mill, and I did not wait until somebody told me how to get it my way.

I took estimates for 100,000 collotypes right away—one from a London firm of printers, and another from a firm nearer home, who both print and publish, and who kept me waiting for about a fortnight, during which time I found that that firm had sent a man here to take a series of views for their own publication and were trying to get them into the shops. I wrote the firm about it, but they tried to smooth me over by saying they did the same in other towns, and pointed out what a large profit I would have, finishing up their letter by asking if I had any negatives which I would care to sell to make up their series.

I took no notice of their letter, but sent the order at once to the London firm, and went round all the shops and made an agreement with them to this effect: that I would supply them with between thirty and forty subjects if they would agree not to encourage outside publishers, at the same time binding all the shopkeepers to sell the cards at one penny each, and one shilling per dozen, so that neither they nor I would suffer from that cut-throat policy of cutting prices.

Six months or so later a firm of publishers wrote me for a set of six negatives, and another firm for a set of twelve, neither asking any questions except the price. I had to hunt through a lot of old negatives which I would never have used, and sent off a selection to each, asking half-guinea for each. The money was back by return of post.

These appeared on the market in due course, printed in colours. I wrote to one firm for their prices, but they would not supply me owing to an agreement with the wholesalers. They evidently did not consider me a dealer. Most of the shops had a supply sent to them unordered, so I just took a turn round the shops and reminded those who had got the coloured cards of their agreement with me. In two cases I withdrew my cards because of their persistence in selling the others, but I considered that I would have more gain than loss. One firm of wholesalers wrote me later for my prices, but I refused to supply them. I still hold the field, and have not much fear of being ousted. I have several other smaller places on the same basis. I do not compel them to buy packets of one of each view, as is usual with wholesalers, but give them any quantity of any view or views which they want, and I find this to be an inducement for them to support me. My cards are not retailed in packets, but customers have their own selection at a shilling per dozen.

Your readers may think that I stand in a unique position by having such a large town to myself, but I "suffer" more from photographers in other towns just at hand sending canvassers to this town. But this is how I "suffer": the canvassers from other towns take away all the third-class sitters, but in this I take a different view from most photographers. I do not reduce my prices and send round canvassers and starve myself, as most of them, I understand, do, but I put from 3s. to 10s. per dozen on my prices and get a better class clientele, more work, and better pay.

"Professional" seems to think that professionals are justified in being averse to the postcard, because it seriously affects his view-selling trade. True, it has entirely killed my view-selling trade (in fact, I helped it), but I make at the very least ten times more profit by the change. You say "you must admit the wisdom of his (the photographer's) hostility to the picture postcard—because that branch of it which includes photographic portraits of celebrities has undoubtedly cheapened photographs in the eyes of the public and has thus lowered the prices obtainable by the less skilful professional photographers." I say it does not follow that the prices must be reduced. I do not use all my skill for my ordinary work, I do the work that I see takes with my clients. But supposing skill is wanting it is surprising what can be done by using the right printing process, using high-class mounts, and raising prices. "Professional" is right in saying that photographers have themselves to blame if they supply postcard portraits at much, if any, below his terms for other work the same size.

It is a great pity that those who do this class of work cannot see the harm they are doing, not only to themselves, but the profession generally. I do not even print real photo-view postcards for the retail trade.

Speaking to a brother professional last summer in a fashionable summer resort, I asked him if he did not publish local view coloured postcards, to which he said "Nah!"—as if such a thing were beneath his notice—and he told me he got an order the year before from one gentleman for 150,000, but he would have nothing to do with it. He has a special line at his very door and takes advantage of it, using whole plates; and it also came out in course of conversation that he sold real photographic postcards from the whole plates. I said that he would require to reproduce his subjects on smaller plates, and was surprised to hear that he did not reduce his plates, but exposed the cards in the camera, giving fifteen minutes' exposure. He seemed pleased at getting threepence each for them! No wonder that some people grow fat at the expense of others.

I do not stick to postcards as the only appendage to my business, but have taken up dealing in cameras and photo-materials for some years, and find it pays well. But of course I do not place my whole rent and expenses against this single line, as "F. M. S." seems to do in his estimate with regard to retailing postcards, which, I think, is preposterous. Mr. Corkett is much nearer the mark; but in this way it is only mere guesswork.

I must apologise for so long a letter, but I hope many of your readers may benefit by a hint or two which they may pick up. I may say that my latest venture is that of publishing a pictorial guide book to a country district (the first of a series, which it is my intention to issue). In fact, my business in this town was a venture, having to build my studio. I was told it was a rash venture, as no photographer had stayed longer in this town than from one to two years before me. I have now been thirteen years here, and feel like staying another thirteen.—Yours,  
POSTCARD.

#### COLOUR SENSITIVE METER PAPER.

To the Editors.

Gentlemen,—With regard to Mr. Terry's remarks at the Croydon Camera Club, we have kept closely in touch with this matter, and if there is any inquiry for paper to fit our meters approximating in colour-sensitiveness to modern colour-sensitive plates, we should soon be ready to supply it. So far, there has been no inquiry.

It must, however, not be presumed that our present "Steadfast" paper is not sensitive to green and red. The enclosed print, under a Chapman Jones plate-tester, shows that it is orthochromatic in character, and a second print of the same paper, specially treated to increase its colour-sensitiveness, shows what we can do in that direction.

We should, by the way, be pleased to send some quarter-plate pieces of our paper to any investigator who has a Chapman Jones plate-tester, and would like to judge for himself.—Yours truly,

WATKINS METER Co.

[The test prints show fair and about equal sensitiveness under the green and red squares.—Eds. B.J.]

#### YACHT PHOTOGRAPHY.

To the Editors.

Gentlemen,—There need be no difficulty in working with a T. and P. shutter provided your correspondent does not attempt anything beyond its capacity. Regarding apparatus. I prefer for work of this class a whole plate box camera. This can readily be slung round the neck, or rested on anything low enough to admit of a clear vision through the finder a few seconds before making an exposure.

An excellent finder can be made by removing the hood from an old-fashioned show "Eclipse" finder, then slipping it inside a

Fig. 1.

Fig. 2.

correctly fitted square tube (as shown in Fig. 2). The upper part keeps off cross light and allows a clear view of the image. Any amateur with a good steady steam yacht ought to secure good pictures; but a rowing boat or small steam launch are too unsteady for work of this sort. Could your correspondent not hire the local water boat or a small cargo steamer, known here as a puffer, for special occasions, as chances from a fixed point ashore are very rare, and it is of the utmost importance to work from a steady base, whether with or without camera stands. I add a rough sketch of my 1/1 camera (Fig. 1), which is very rigid and without complicated movements. The shutter is an original "Kershaw" working behind the lens. The two screws (of which only one is shown) at the side of the shutter fix the vertical movement at any point. They also allow the lens to swing at right angles with its own axis at any elevation. The rack and pinion in the base admit of

careful adjustment to a previously marked scale on the baseboard, and for yachting subjects beyond 100 ft. it is quite enough to extend the camera to a fixed focus, which may be determined at  $f/8$  on any clearly defined object at 80 or 100 ft. By using  $f/11$  for dull subjects or  $f/16$  for brilliant ones, everything will be sharp from 70 ft. to infinity. The finder must be carefully corrected for covering power of lens, and this will show clearly the subject up to the moment of exposure. It takes a good deal of knowing to be successful, but there is a great deal in being master of the situation and able to take full advantage of an unlooked-for opportunity.—Yours faithfully,  
BHAM-O.  
Oban, Scotland.

#### SULPHIDE TONING OF BROMIDES.

To the Editors.

Gentlemen,—In reference to the recent difficulty of a correspondent getting the bleached print to darken in the sulphide solution, an examination of a print sent to me by yourselves has shown me that very common event in sulphide toning has taken place.

The hypo in the decomposed sodium sulphide has rapidly dissolved the haloid formed in the bleaching, allowing only of the smallest amount of silver sulphide being formed. Some sulphide has been removed, and this constitutes what image there is. My reasoning is as follows:—1. All tests prove the complete absence of any haloid.

Hypo will not affect the image in any way. 3. Potassium cyanide completely removes the image; therefore, as potass cyanide is a solvent of silver sulphide, I take it for granted, without further analysis, that the faint image is composed of silver sulphide (or Carnegie's modification).—Yours truly,

C. WINTHROPE SOMERVILLE.

Lyrath, 117, Hazelbank Road, Hither Green, S.E.

#### PHOTOMICROGRAPHY AND MULTIPLE COLOUR ILLUMINATION..

To the Editors.

Gentlemen,—Referring to the article on the above on page 157 of our issue of March 1, may I be allowed to trespass a little on your space to prevent any misconception?

Whilst multiple colour illumination is based upon the same broad principle—viz., the desirability of securing the best contrast between object and background to secure the best definition—upon which the work of Dr. E. J. Spitta and Dr. C. E. Kenneth Mees has been done, it differs very materially in other respects, in fact their work and mine, one might almost say, has been of a complementary nature.

The problem that these gentlemen set themselves and which they have so skilfully solved was taking objects which, seen usually, are stained or coloured, to secure the best contrast in black and white on the photographic plate. This they do by means of uniformly coloured light filters, the selective absorption of the stained or coloured object being the special factor utilised.

My problem was to take uncoloured or unstained objects, and secure the best visual contrast in colours. This has been effected by means of circular discs—the peripheral portions of which are differentially coloured to the central portion—and the factors principally utilised in obtaining the desired result are the refraction and diffraction of light by the object.

As regards the application of multiple colour illumination to photomicrography, I am hopeful that it may prove of value for colour photo-micrographs, though, so far as I know, nobody has as yet applied it to this branch of work. As for photo-micrography in black and white, I have come to the conclusion that no special advantages are to be gained by illuminating the object and background in different colours, as so far as the desired results are concerned, they can be obtained more simply.

To take just one concrete example. A slide of diatoms or foraminifera viewed with a double-coloured disc by the refraction method, so that the objects are seen in red on a green ground, would give visually an excellent contrast effect—photographically the simplest way of obtaining an equally good result, would be to use the ordinary dark ground illumination, and employ a uniformly coloured blue or violet light filter, such as Wratten and Wainwright's with an ordinary non-orthochromatic plate.—Yours truly,

JULIUS RHEINBERG

16, Coolhurst Road, Crouch End, N., March 5, 1907.

## Answers to Correspondents.

\**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

\**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

\**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*

\**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

#### PHOTOGRAPHS REGISTERED:—

J. HARGREAVES, 4, Fair View, Dalton-in-Furness. *Photograph of Usterston Town Football Club.*

J. C. LELIE, 23, Alderbank Terrace, Merchiston, Edinburgh. *Five Photographs of Views of the Craiglockhart Ponds, Colinton Road, Edinburgh, with skaters thereon.*

BOOK ON LIGHTING.—Would you kindly recommend me a good book on studio lighting, one that shows how the light may be controlled with the use of blinds.—H. LENOTT, Malmesbury, Cape Colony.

"The Photographic Studio." By T. Bolas (2s.), or "Lighting in Photographic Studios," by P. C. Duchochois (1s.). You may obtain either from Dawbarn and Ward, 6, Farringdon Avenue, E.C.

R. P. S.—Kindly let me know if it is possible to become a member of the Royal Photographic Society, and how to go about it, please. If not, is there any other British society I could join?

C. PURNELL PARKERSON, Potorna, Auckland, N.Z.

Application should be made to the Secretary, Mr. John McIntosh, 66, Russell Square, London, W.C. We have asked Mr. McIntosh to forward you the form of application. If you are a professional photographer it is to your advantage to join the Professional Photographers' Association. The Secretary is Mr. A. Mackie, 89, Albany Street, London, N.W.

TIME DEVELOPMENT.—1. Would you kindly give me a formula for a suitable developer for time development, one giving a negative of medium density in about ten minutes, at, say, 70 deg. Fahr.? I would prefer one that could be conveniently stored in concentrated solutions, and not liable to deteriorate too rapidly. 2. Given ample washing between operations, do you think harm likely to result from using the same article for developing and fixing? 3. Can you give me the name of any book containing information as to time taken by various developers, at given temperatures? The details given in the books I possess are altogether too vague for practical use.—F. W. BRADBURY, Eastern Telegraph Company, Ltd., Gibraltar.

1. We should advise the use of rodinal or a paramidophenol solution of the following composition:—

Paramidophenol hydrochloride .....	1 oz.
Potassium metabisulphite .....	3 ozs.
Water .....	10 ozs.

Dissolve and add:

Caustic potash, sat. sol. .... g.s.

to dissolve the precipitate first formed. This will keep indefinitely, and may be diluted for use in the proportion of about 1:60 for ten minutes' development at 70 deg. Fahr. 2. As long as the washing was sufficient no harm would accrue, but we must confess to not liking this method of working. We should feel safer if a hypo elimination, like potassium permanganate or hydrogen peroxide were used to clean the tank in between fixation and the next development. 3. There is no book on the

subject, but an article appeared on p. 249 of our issue of March 31, 1905, and an abstract of a later paper by the same authors, Messrs. Ferguson and Howard, appears in the "Almanac" for 1907, p. 754.

**BOOKS ON PHOTO-MECHANICAL SUBJECTS.**—I should be glad to have names of two or three manuals (pratiques) on phototype or colotype, as I have some zinc plates and a press at disposal—I mean gelatine and bichromate process. German books are often more complete and precise in details; the language presents no difficulty.—**PHOTOPHIL** (Tunis).

For colotype, we should recommend "Der Lichtdruck," by August Albert, published by Wilhelm Knapp, of Halle. For phototype, "The Half-tone Process," by Veriasser, published by Iliffe, London, price 5s.; or "The Half-tone Process on the American Basis," by Cronenberg, price 2s.

**STUDIO LIGHTING.**—I remember reading an article in the "B.J." somewhere towards the close of 1905, relating to an idea of studio lighting by means of a square system. The author claimed to be able to get proper lighting, even though in every case he made it mechanical: as he used his square of light larger so he moved the sitter further away, and so on. The article rather impressed me, and I intended to keep the number and give it a trial; but now, although I have a big pile of the *JOURNAL* on hand, the particular number I wanted must have been lent. I would therefore, be obliged if you would send me the number containing this article.—**W. H. GILL**, Middleburg (Cape), South Africa.

We cannot trace the article in our pages for the period to which you refer. There was an article which answers to the description by F. M. Steadman in "The Photogram" for April, 1902. We have asked Messrs. Dawbarn and Ward, 6, Farringdon Avenue, to send you a copy.

**ENLARGEMENT CYLBS.**—Can you give me a little information how to work a club for photographs or enlargements, or give me any address where I can obtain the necessary rules?—**F. FUTCHER**.

We know of no rules of the kind. We should advise you to apply to one or two firms supplying enlargements for club purposes. You will find the advertisements of a number in our columns.

**COPYING OIL PAINTINGS.**—Would you kindly tell me how best to copy old oil paintings, which plates to use, etc.? Can get very little result on ordinary plates.—**OIL PAINTING**.

To obtain satisfactory copies of oil paintings and all coloured objects it is essential to use colour-sensitive plates. If there are no browns or reds in the picture then an ordinary ortho plate with a deep yellow filter may answer, but much more satisfactory results can be obtained in all cases with a panchromatic plate and a yellow filter. Special filters, which give reproduction in correct luminosity of all colours are advertised in our pages, but it may sometimes be advisable to sacrifice a little correctness in order to ensure contrast between two colours. This is entirely a matter of personal opinion.

**COPYRIGHT.**—Will you kindly answer the following in the "B.J." this week, as it is a most urgent case? I have taken the photograph of a young lady. Some one has copied same and printed and finished them. The young lady's parents are indignant, and thought I had sold them. They wish me to stop them. Can I take proceedings against the offenders?—**A. K.**

If you were paid for taking the photograph the copyright in it belongs to the person who paid you—that is, the young lady, her parents, or whoever paid you for the work. They can register the copyright at once and stop the further sale or exhibition of the photograph. If you received no payment the copyright is yours, and you can take the same steps. You had better refer to the article on "Copyright" in the 1906 "Almanac," for your present and future guidance.

**HALF-TONE PAPER, ETC.**—1. Where can I obtain Lindenmeyr's half-tone writing paper mentioned in "Ex Cathedra," "B.J.," February 22? 2. Please give addresses of some wholesale bottle manufacturers (I require bottles suitable for retailing developers, etc.).—**HILL-Top**.

1. Messrs. Lindenmeyr's address is Upper Thames Street, E.C. If as wholesalers they will not supply you with the paper, they will give you the name of an agent. 2. H. Poths and Co., 5 and

6, Bury Court, E.C.; and F. H. Taylor and Sons, No. 1 Wharf New Wharf Road, King's Cross.

**PHOTOGRAPHS FOR SALE.**—I have some interesting little bits of country scenery, and also picturesque photographs of country cottages, which I wish to turn to some account. Are such pictures much in demand for postcards? If so, to whom would you advise me to sell them? If of no interest except as a picture, would they be of use to the Press? Also, which postcard producer would be likely to buy photographs of cats and dogs, etc.?—**L. M. C.**

We advise you to submit a selection to the leading postcard publishers, whose names and addresses you will find in the "Picture Postcard and Collectors' Chronicle," 42-44, Imperial Buildings, Ludgate Circus, E.C. It is impossible to name a publisher as specially likely for a given class of subject. As regards the Press, it is impossible to say. We advise you to study the elements of this branch of photography, as you may do in "Photography for the Press" (Dawbarn and Ward, ls.).

**DAGUERREOTYPES, ETC.**—1. Please let me know where I could obtain an apparatus for taking, developing, and fixing Daguerreotypes in one. 2. Also where I could obtain colour transfers to make lantern slides.—**JOHN R. CAVEDASEA**.

1. It is not possible, so far as we know, to obtain any Daguerreotype apparatus of any kind now, except by chance at some second-hand shop. So far as we are aware, there never was an apparatus made to do all the operations in one, nor is it practicable. 2. Try W. Butcher and Sons, Camera House, Farringdon Avenue, E.C.

**COLLODION PROCESS.**—Kindly give me through the *JOURNAL* a formula for bromo-iodised collodion for wet plates for lantern transparencies, as I have mislaid my formula. In *JOURNAL* of February 22, there is one, but to me it seems too weak in bromides. Is not the developer in same incorrect, viz.:—

Iron sulphate .....	1 oz.
Acetic .....	1 oz.
Water .....	1 oz.

I have been experimenting with some collodion made with Schering's cotton (in shavings), which have given much superior results than the ordinary cotton, and which gives films free from structure.—**W. B. WOOD**.

The formula to which you refer is a very good one. It gives 1 grain of bromide to each ounce of collodion, which is ample in the wet collodion process. There is a printer's error in the formula for the developer; instead of 1 oz. of water, it should be 1 pint—or 20 oz. The mistake was corrected in our last issue. Would it not answer your purpose to buy the collodion ready for use rather than to prepare it yourself? If you do that, you will ensure having what is suitable for the work.

**ENLARGING APPARATUS.**—1. I am about to fit up some enlarging apparatus (artificial light). Would you kindly inform me what I can get particulars and sizes for making a suitable enlarging table. 2. Also can you give me any hints on purchasing a condenser—what to avoid, etc.?—**A. S.**

1. In "Photographic Apparatus, Making and Repairing" (Dawbarn and Ward, ls.). 2. We advise you to get the usual pair of planoconvex lenses. No further advice can be given.

\* \* **NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

In this week's editorial we emphasise the importance of a photographer keeping a system of accounts sufficient to enable him to check the variations in his business. Our notes are introductory a series of articles dealing, in as brief a space as possible, with the actual form which such book-keeping may take in the case of average medium-sized business. (P. 191.)

Messrs. Horace C. and Conrad Beck provoked an interesting discussion at the R.P.S. on Tuesday last by their account of a new anastigmat lens (the Isotigmat), possessing very high corrections though not fulfilling the Petzval condition. (P. 205.)

Messrs. John J. Griffin and Sons, Ltd., on Wednesday last obtained a large company at their new house in Kingsway, on the occasion of the formal opening of a new demonstration gallery and information bureau. (P. 198.)

Mr. Henry C. Spink, of Brighton, has been elected president of the P.P.A., in succession to Mr. Martin Jacolette. (P. 199.)

The first instalment of an article on the photography of machinery and engineering subjects appears on page 197.

The cause of the greater chemical fog on an unexposed plate in comparison with one exposed has been sought by MM. Lumière and Ewertz in the lack of liberated bromide in the former case. (P. 195.)

The virtues of artificial light in the studio are discussed at some length by an American writer and worker. (P. 194.)

Further details are published of the dye process of Dr. Traube, in which silver iodide is used as a base. (P. 196.)

Mr. Gorell Barnes has announced his determination to exclude photographers and draughtsmen from his court. (P. 199.)

The contents of the week include a folding camera, daylight development, and colour photography. (P. 200.)

## EX CATHEDRA.

### How their Leaders Work.

The forthcoming conference in New York of the Professional Photographers' Society of that State, is, as we have already intimated, to be the occasion of a series of demonstrations by acknowledged leaders of the profession in their own studios. The humbler members of the Society are to have the opportunity of seeing Hollinger, Core, Rockwood, Garo, Bradley, and Falk at work in their accustomed manner, and the visit to each establishment is to be made a demonstration of the particular class of work on which the several photographers rest their reputations. Thus Core will have children for his sitters, Garo will demonstrate the photography of draperies, Rockwood will work by artificial light, and Hollinger will deal with the simple poses of heads which characterise his work. The number of visitors in each case is limited to fifteen, and in recognition of the courtesies due to the country members of the Society, as well as to the demonstrators, members residing in New York refrain from applying for admission. The idea, which some day may be applicable in this country, evidently forms a strong incentive to a good attendance at the conference.

### A Word of Advice.

The queries which are continually addressed to us on copyright matters show no signs of diminution, and no doubt those of our readers—and we believe they constitute a considerable proportion—who read queries and replies week by week out of curiosity, discover some amusement in the repetition of inquiries which as likely as not were answered in the very week during which the reader addressed his letter to us. But if the knowledge of copyright law is limited among the less studious number of our readers, the possession of tact in making use of the acquired knowledge is rarer still, and we have reason to know that a professional photographer's difficulties have been increased instead of diminished owing to the high-handed action he has taken when told that the supposed infringement is actually a case for legal action. Among the good resolutions which a photographer can make there is none which will profit him more than to allow his copyright disputes to be dealt with by the Professional Photographers' Association, of which body he should, of course, be a member, or, if the Association does not regard the case as one which it is wise to take up, to be guided by its advice. Many men in business at the present moment would have saved pounds had they heeded and taken this advice.

### The Non-Return of Specimens.

We hear less than we did at one time of specimens being retained by persons or firms to whom they are submitted by applicants for a situation. It will be remembered that we

have cautioned our assistant-readers against sending specimens to box numbers at our office, and no doubt this fact and our publishers' refusal to insert requests for specimens in advertisements appearing under a box number, have reduced the evil to small dimensions. As in all other human affairs, there are two sides to the question, and we have had instances brought before us in which employers who had been accused of retaining specimens were doing so for want of marks on the photographs identifying them with the applicant. Some years ago we published some hints to applicants, one or two extracts from which we may with advantage repeat:—

1. Write clearly and to the point. Answer all the queries in the advertisement.

2. Enclose a stamped envelope for a reply.

3. If enclosing a portrait of self, let the sender's name be upon it.

4. In sending specimens, let stamps for return invariably accompany them, with also a suitably addressed wrapper for their return.

5. Let every specimen have its owner's name (and preferably address) written plainly on some part of the picture or mount; if on the picture itself, there is little danger of dishonest persons retaining them.

\* \* \*

### Composite Developed Images.

Mr. Sterry, in his paper on "The Action of Oxidisers on the Development of the Latent Image," read at the R.P.S. and reported on p. 165 of our issue for March 1, stated that he had been led to the view that light produced three products or practically three latent images. In connection with this hypothesis, it is interesting to note that the finished negative contains more images than one, the traditional single image of pure silver in clean gelatine being apparently a myth. There is a main image in silver that can be removed by a silver solvent, but there is also a residual image of mysterious composition that is unaffected by the silver solvent (excepting, perhaps, when cyanide is used) insoluble in hypo, and practically undevelopable. In a negative made on an ordinary rapid plate this residual image is almost invisible but still detectable. In a "gaslight" lantern plate it is obvious, and looks very much like a weak sulphide-toned image. It is evidently of a complex nature, as silver compounds can be found in it. To a certain extent it can be chlorised and either redeveloped or dissolved in hypo, but the actions are only partial. It is, of course, difficult to determine when the image comes into existence. It may be a result of development, or it may have existed prior to development. If iodide existed in the emulsion it can generally be found in the residual image in an insoluble form, and if the developer gives an organic deposit, that also can be found. But even when both these constituents are avoided, the image still exists. Whether it has any bearing on Mr. Sterry's theory or not, it appears to us that further investigation of this residual negative image is desirable. If such investigation does not add to our knowledge concerning the latent image, it may give some information with regard to little-known silver compounds, and no item of information is too small to be worth consideration in the domain of photographic chemistry.

\* \* \*

### Store Competition in Photography.

If our New York contemporary, "The Photographer," were able to observe professional photography in this country it would probably sound a less alarmist note than that which it is prompted to emit in its current issue, because competition with portrait photographers is being actively put forward by New York stores in the shape of cabinet photographs at a dollar a dozen. If the

American photographer has nothing much worse than this from the competitors outside the business he need not begin to grumble—time enough for that when "free portraits" from religious papers and beef extract companies have made inroads in his territory. According to our contemporary, a policy of retaliation, adopted by photographers in concert, will provide a remedy: "If the various local organisations of photographers would band together to fight this 1 dol. business and, in combination, also offer 1 dol. pictures, advertising the offer through the papers and in other ways, each member of the organisation being taxed *pro rata* for his share of the advertising expense, this 1 dol. rate would soon cease, for the public would undoubtedly rather go to the regular studio, all things being equal. The public would rather have the signature of a regular studio than that of a department store at the foot of its pictures."

\* \* \*

### Extra "Wall Space" at Exhibitions.

Hanging committees of the smaller societies, to whom the necessity of rigorous selection does not apply with such force as it does to the better known exhibitions, may at times be at a loss for space sufficient to display the whole of the selected frames. Under these circumstances they may be glad to make a note of an expedient which we remember having seen in practice several times, and which consists simply in the manufacture of a few frames from wood about a couple of inches wide and  $\frac{1}{2}$  in. thick, with one or two cross-bars for the sake of strength. An amateur carpenter with a hammer, saw, and a few nails will put the affair together in an hour or two, and the frames will support themselves like a clothes horse if hinged together with strips of webbing. They may be covered with materials, fitting the mural decorations, a matter of little difficulty if the fabrics from such firms as Burnetts of Long Acre be requisitioned, or even sheets of the stouter mounting papers might be employed. A professional photographer anxious to make a special feature of new work might do worse than instal a similar device into his establishment.

\* \* \*

### Important and Interesting.

The recent discussion at the annual general meeting of the Royal Photographic Society on the improvement which might be made in the "Journal" of that body was forcibly brought again before us on our turning up during the past few days a back number of the journal of the Camera Club, in which was an article by Sir William Abney dealing in very readable and humorous fashion with the theory of the latent image. To invite the reader to understand a possible change caused by light, imagining the chemical bodies to be partners in a dance, some staid and respectable and others more volatile and lively, was a happy inspiration which might be breathed again with advantage upon the text of some of the papers which are delivered to a listening world at 66 Russell Square. Is it too much to hope that Sir William who for some years has assumed responsibility for the contents of the Royal Photographic Society's journal, may persuade some of the readers of papers to take a leaf out of his book of ten years ago?

—♦—

THE LATE MR. M. L. ISAACS.—We regret to record the death, on March 2, of Mr. Meyer Lewis Isaacs, a director of the firm of Houghtons, Ltd., and formerly head of the firm of Joseph Lee and Co., Hatton Garden, the affairs of which branch of Houghtons Ltd., the deceased gentleman superintended up to within a few days of his death. Mr. Isaacs' death will be felt throughout the trade where he was greatly respected.

## BUSINESS METHODS IN THE STUDIO.

the railway ticket-collector who, so it is said, for lack of definite instructions on the point, declared "dogs is cats and cats is dogs, but tortoises is hinsects," would, doubt not, be in a like dilemma had he to determine whether the professional photographer is following an art, a business, or a trade. The good photographer rightly regards himself as an artist, but, inasmuch as professional photography involves the purchase of materials, and, generally, the employment of hired help, the cost of both which bears no small proportion to the amount obtained for the photographs, he is to that extent a business man, and should therefore follow what are generally known as business methods in his studio. However uncongenial attention to detail may be to the artistic temperament, stress of competition makes insistent demands that the studio shall be conducted on business lines, and unless be one in which there are two or more partners, one of whom can devote himself to the business side, the proprietor must endeavour to combine in himself the qualities of business man and artist.

Let it be distinctly understood that we do not wish to detract from the dignity of professional photography in the slightest degree when we plead the necessity for thus combining the commercial with the artistic. Photographers so closely into almost every phase of the complex civilisation in which we live, that the photographer who would be in the front rank must, of necessity, conform to prevailing conditions. In an age which is frankly commercial, he must be commercial, too. But it need not be at the expense of professional dignity.

Mr. Charles Wesley Hearn, the President of the P.A.A., expressed it, when he foretold the success of the moving-picture exhibition of the Professional Photo-

graphers' Society of New York, on the ground that "the professional, if he be sane, must always remember that *his profession is a business*, and that just as much attention must be paid to business as to making pictures, and that both of these attributes are combined in the exhibition."

If this be so, it follows that business methods should be employed in the studio, methods which will ensure systematic dealing, not only with sitters and employees, but, most important of all, the photographer's own affairs—in other words, there should be an efficient system of accounts.

In a great many studios no proper system is in force, and in those in which one is most needed there is none at all. How often does one read in the reports of bankruptcy proceedings, "Debtor does not appear to have kept any books"; "he did not realise that he was insolvent until the principal creditor obtained judgment." The owner of a studio which is known to be paying may urge that he is careful to live within his means, and therefore has no need to keep accounts; but there are many reasons why he should do so. In the event of his wishing to sell or, after his death, his executors wishing to do so, a set of accounts that can easily be verified is of immense value. So it is, too, in dealings with the Income Tax officials. Again, a business of any kind rarely, if ever, remains stationary. It either grows or diminishes, and, although one may be very observant, it is extremely difficult, in the absence of proper accounts, to determine in which direction a business is moving, especially when credit is both taken from manufacturers and given to sitters. Having thus suggested the desirability of keeping proper accounts, we now draw attention to the first of a series of articles, giving directions for keeping such records as will suffice for the requirements of the average studio.

## BUSINESS METHODS IN THE STUDIO.

### I.

we will assume, for the purpose of these notes, that we are dealing with the studio of Mr. A. Darkslyde, a photographer besides devoting the whole of his time to the business, employs an assistant operator and a receptionist, sharing out touching between them, a girl for mounting and spotting, a girl, and a boy—a total wages bill of £6 10s. per week.

Mr. Darkslyde will, of course, keep a sittings book or studio register. Fig. 1 shows a good form of ruling, providing as it is a record of the whereabouts of negatives and the time taken with any order. It will be noted that there are no columns—the reason for this will be explained later. For the studio register, Mr. Darkslyde will require three small account books—the day book, the cash book, and the petty cash book—in addition to the petty cash book and the private

### Taking Stock.

The first step is to take stock. On the one hand Mr. Darkslyde sets down all his liabilities, that is to say, everything he owes; and on the other his assets. These latter include the value of the premises if they are his own property, the apparatus, the stocks of materials—plates, papers, and chemicals—the amounts owing to him by customers, and the amount of cash at the bank and in hand. The surplus of assets over liabilities is called Mr. Darkslyde's capital, and a complete statement constitutes his balance-sheet. If, at the end of a year, another balance-sheet be prepared, it may likely be found that the capital is less; the amounts

due to creditors may be more, while those owing by sitters are less, and the cash balances are also lower. This is either a sign that the business is not paying so well, or else that Mr. Darkslyde has been drawing more money from the business than the profits warrant. Thus it is that stocktaking is so valuable; it enables a man to know exactly how he stands, and gives, it may be, a timely warning that retrenchment, in some form or another, is desirable. The stocktaking, of course, does not show how the results of the year's trading have been arrived at. The accounts must furnish this information.

### Simple Account Keeping.

The following system is simple. It assumes that Mr. Darkslyde not only has a banking account, but that he is willing to pay in all cash he receives to the bank, and also to make all payments by cheque, sums less than, say, twenty shillings being paid from the petty cash, which is sustained by amounts of £5 at a time as occasion requires. The writer knows that many photographers of his acquaintance have no banking account, but, as has already been said, the photographer ought to be a business man, and a banking account is a business facility of which he should not fail to avail himself.

### The Daybook.

Some photographers endeavour to combine the day book and the studio register, but the plan is a bad one. A sitting, given upon an order for only a few shillings, may, under favourable circumstances, run into as many pounds. The studio register

book. If there be any discrepancy, the items in the pass book should be run through, when it will be found that the bankers may have entered a few charges, the cost of a new cheque book, commission on out-of-date postal orders, and so on. These amounts should be entered in the cash book under the sundry expenses column. If the pass book balance exceed that of the cash book, it is most likely owing to a cheque drawn near the end of the month not having been presented for payment. Any differences beyond these should be looked for carefully. They may be the results of clerical errors—very occasionally on the part of the banker—or they may be actual mistakes in the money itself, mistakes which should be investigated at once.

good many entries, while it is an easy matter to place a new card in the fortunate event of one ever completely filling.

Each day the entries in the day book and the cash book are posted to the ledger, the former to the left-hand, or debit, column, and the latter to the right, or credit, column. If, instead of the conventional "To goods" of the debit side, we substitute the order number when posting from the day book, we at once introduce a time-saving feature, because, in the event of a sitter re-ordering at any time, the one reference to the ledger gives the order number in the register, with its full particulars of the original instructions.

Monthly or quarterly the accounts are rendered to sitters from the ledgers, and the amount is jotted down in pencil,

### The Ledger.

This book is, of course, the record of the accounts with the sitters. It may be the book form, known to most of our readers, or it may be the comparatively unknown card ledger. The card ledger is far preferable in any business involving a number of accounts with but a few transactions in each. Each sitter has a card headed with name and address, and these are filed alphabetically, cards called guides, with projecting tabs on which are written the letters of the alphabet to facilitate reference, being inserted in their proper positions. A rod runs through the holes at the foot of the cards, screwing the back of the drawer in which they are kept. The cards are ruled both back and front, so that there is room for a

so that if it be not settled before the accounts are again sent out (an experience which is, unfortunately, only too common) this amount heads the account, "To account rendered." At stocktaking time all accounts are closed, and the amounts of the balances needed to make the two sides agree are brought down. It may happen that a sitter has paid a deposit, and thus the balance will be on the opposite side to that of the majority. Such a one will, as far as the accounts are concerned, of course, be a creditor, but these items may be provided for by reckoning them as work in course of completion, as will be shown next week, when we propose dealing with Mr. Darkslyde's profit and loss account.

S. E. KAYE.

**PHOTOGRAPHERS** will probably be interested to know that the Service Company, Ltd., of 292 and 293, High Holborn (with which the Service Photographic Society is associated), are holding an exhibition at the present time of cycles and the accessories relating to them. A special display will be made at the same time cameras and accessories which can be used in conjunction with cycle.

**MARTIN AND CO.**—The business of Messrs. J. Martin and Co., enlargers and printers, of New Southgate, is to be carried on by Martin, Godwin, and Co., under the management of Mr. Stanley Godwin. The new firm has improved its means of dealing promptly with high-class trade work, and invites inquiries from dealers and trade generally.

**THE "STANDA" DAYLIGHT DEVELOPMENT TANK.**—The Standard Patents Company, Ltd., of 11, Bond Court, Walbrook, London, E.C., write as follows:—"We beg to inform you that we have acquired the patents controlling the 'Standa' Daylight Time Development Tank, which, as you may be aware has now been on the market for a couple of years, with an ever-increasing popularity. This season we are issuing the tank with several improvements. Will you be good enough to notify your readers that we shall be pleased to demonstrate the tank at the above address at any time during business hours, and to develop any plates brought for the purpose for the bare cost of the chemicals used? Messrs. Houghtons, Ltd., who have been associated with the 'Standa' tank from the first, will continue, in conjunction with ourselves, to supply the trade."

## ARTIFICIAL LIGHT VERSUS DAYLIGHT.

[The following observations of the comparative efficiency of the two sources of illumination which appear in "The Camera" under the signature of a very well-known worker in professional photography should provide some thoughts for consideration by those who have not adopted artificial light in their businesses.—Eds. "B. J."]

WELL, the time has come when the question is being asked "Do you think artificial light is better than sunlight or daylight?" A few years ago we should have laughed at this question and treated it as nothing more than a joke, but to-day it is no joking matter, and in my humble opinion within five years there will be more artificial lights used than the oldtime skylights. It is surprising how anxious the photographers are to become independent of "old Sol." The operator swears at him when the day is dark, the printer joins in the chorus, and the "boss" stands off and applauds them both, for he knows he is losing trade by the bad weather. When the public realises the fact that the operator is able to make as good work on the cloudy day as on the clear, it will begin to come into the studio on those days, and there will be no dull days and no unprofitable ones; all will be the same. Notwithstanding the fact that photographers have advertised that "cloudy weather is as good as sunshine," if they will but be perfectly honest for a moment, they will have to come right down to brass tacks and acknowledge that cloudy weather is *not* as good as clear and that the work done on those days is not so good. We have tried to convince ourselves that it is as good, for many years, but have never been fully convinced, and neither has the dear public.

### It's all in the Operator.

But now come the artificial lights, and all we have to do is to press a button or turn a crank and on comes the light; then we go ahead, and the negatives come the same one day as another. Now comes the question that I expect to answer, "Do you think artificial light better than daylight?" And to this question I answer: "Nay, nay; but I do think it more uniform than daylight, and I do think it as good as daylight, but not better." This brings me back to the old assertion that I have made so many times through the columns of "The Camera," "that one light is as good as another if the operator is as good as the other." It's all in the man, and if the man can work one light he can work any other light; but if he falls down on one light he is as apt to fall down on some other light. If he can control one light and make it give him a certain effect, he can control another light and get the same effect. If he comes up under a certain light and says, "I cannot get that effect under this light," or "I cannot get that effect here," he is lacking just that much of being a good operator. If he comes up "bright and smiling" under any light and gets the same effects every time, it may be taken for granted that he is a man who knows what good work is and how to get it, and if he cannot have a pet light he will make one that is not a pet do the work for him.

So it is in the use of artificial light. The operator who can work any skylight will have no trouble in working any artificial light that is on the market at the present time for that purpose. I make special mention here of the "Aristo" light, simply for the sake of convenience and for the reason that I have worked that light and know what it will do; but at the same time I desire to say I think there are other lights that will produce as good work and that are just as easily controlled. The use I have made of this light has convinced me that I can get anything with it that I can get with daylight. The one question that seems to be in the minds of all operators is that it may not work as rapidly as daylight, which would, of course, necessitate a longer exposure, and hence be not so good for work with children or short exposures generally. This is not my experience, for I have found that the exposure can be made quicker than with the average skylight. The exposure by this light can be governed

largely by placing the subject farther from or closer to it. Often in the working of a skylight we find the operator stopping his lens down to control the exposure; he knows the plate will be overexposed if the lens is used open, and not having his light curtained, so that he can close off part of it, he must control the exposure by stopping down the lens. This destroys one of the most pleasing effects in portrait work. When the lens is stopped down to any great extent it destroys that warm, fluffy, atmospheric effect that all good operators like to have their work show. This atmosphere makes the portrait look as if there are certain parts that are nearer than other parts, and so we get the right idea of distance and perspective. This is all destroyed when we begin to stop the lens down, for to stop it down makes the lens cut deeper, and in doing that it brings all parts up on the same plane, making what we call a "flat field." This is anything but desirable in portrait work. It is often impossible to move the subject away from a skylight owing to the fact that the room is so narrow that we have to confine ourselves to a limited space, hence the stopping down of the lens.

### The Effect of Distances.

With the artificial light this is overcome, for the light can be raised or lowered and the subject moved away from it until the exposure is controlled, and at the same time we preserve the atmospheric effect that is so much desired. Any operator who understands the use of the flash machine will understand this condition and be in position to make the most of it. He will remember that the farther from the subject the flash machine is placed the softer the effect of the light and the more powder he must use. So it is with the artificial lamp; the farther from the subject it is placed the softer the effect and the longer the exposure that must be given. Therefore, it will be readily seen that the exposure problem is entirely in the hands of the operator, something that cannot be said of the old-time skylight. There has never been an operator who had complete control over his light when it came to exposure. There are too many conditions governing the exposure problem for him to get complete control of it, and chief among the conditions is the constantly changing intensities of the light. One minute the sun is out strong, the next it has softened considerably, and the next it is cloudy; so on during all the day, so that the operator is never making the same exposure, and when he comes to developing he has to manipulate the developer for every batch of plates—or, at least, he thinks he has to manipulate the developer. With the artificial light the intensity of the light is the same all the time; and if the operator will experiment just a few minutes he will find the distance it should be placed from his subject to secure the same effects at all times and then keep the lamp there all the time, and he will have the exposure problem in his hands so far as the light is concerned. The distance the light should be from the subject will be governed by the lens to be used. Some lenses work at  $f/4$ , and with a 16-inch focus will, of course, work very much faster than a lens working at  $f/8$  and 16-inch focus. So the operator should have the lamp placed where he can get the exposure he wants to give and there leave it. I have an  $f/4$  lens, and the lamp, when in use, is placed so that it is about seven feet from the top of the subject's head, and the average exposure is about one second. This would be the average exposure under a skylight measuring sixteen feet square, where there were no obstructions to the passage of the light to the subject; so it will be seen the lamp works as fast as any other light.

### The Benefit of a Concentrated Lighting.

One other advantage I see in the lamp is that its light is a more concentrated light. I do not mean it is harsh, for it is nothing but that; but, being small, it concentrates the light at those parts at which we want it concentrated and then blends it in a soft effect to all the other parts. This is especially noticeable in the lighting of white draperies. I suppose by this time the readers of "The Camera" have found that I am somewhat of a crank on the subject of lighting white draperies. Now, this light is fine for that part of the lighting. I have not found it necessary to use any of the screens that I used in the skylight lightings to control the light on the lower parts of the figure. The light concentrates at the face, and that is the highest point of illumination, and from there it is a gradual reduction to the lower parts of the figure. This is as it should be, for all operators know their great trouble in lighting white draperies has been to keep the white dress from coming up so fast in the developer that it would give nothing but a white (blank) effect in the finished picture. There have been many methods resorted to to overcome this effect. One was to place a screen between the subject and the light, so that all of the direct light, striking the subject, would have to pass over the top of the screen and then bend downward in a soft, diffused way to the lower parts, and I have found very few operators who could do this with any degree of success. Another method was to locally reduce the white parts after development, and I have found fewer still who could do this. With the artificial light it is not necessary to do either. The subject should be placed so that the lamp is about seven feet more or less, according to the length of exposure the operator wants to give) from the top of the subject's head and raised to a point where it will throw the light on the face from an angle of about 45 degrees. This is another thing the readers have found that I am a crank on. I am most positively a crank on having the light fall on the subject's face from an angle of about 45 degrees, if the picture is to be a portrait. If it is a genre picture it may be different—but that's another story. The lamp should be placed to the front of the subject, so that if he were to close the eye on the light side of his face and try to see the lamp with the eye on the shadow side of his face he could see the entire lamp. If the operator has any doubts of the position his subject should occupy in relation to the lamp, let him take the

seat to be occupied by the subject and experiment until he gets the lamp in the right position. When he can see the lamp with the eye that is on the shadow side of the face he has it placed at the right point in front of the subject. Next he should raise the lamp as high above his head at this point as he can without losing sight of it with the shadow eye. This will place the lamp at the right height to secure the angle of 45 degrees. Now, if he has the subject seated at this point he will get what is known as the portrait effect of light, or broad effect some call it. From this time on he can move his camera from one side of the subject to the other and get anything from a broad effect to a full profile Rembrandt effect, as it is called. Now, for the exposure all he has to do is to remember the exposure for a broad effect, and it will be the same on all occasions. Then remember the exposure on the Rembrandt effects and they will always be the same. So he has the exposure problem in his hands. Now, if the temperature of his developer and its strength is the same, he will have no trouble in following the "tank development" system and developing all his plates in one solution and at one time. The artificial light is destined to simplify the work of the photographer, making it possible for him to make his negatives by it, retouch them by it, and at last to print them by the same light and be able to do the printing at any "old time." It not only makes it possible for him to do these things, but he can so plan his exposure and his developer according to the exposure that he can place fifty negatives into the same solution and leave them for a given time, and when he looks at one, and that one is finished, he can, without taking the trouble to look at the balance, take all out, for they all, having received the same exposure and having the same developer and the same temperature, must develop the same. "Is artificial light better than daylight?" Well, no, not so far as effects in light are concerned, but for the many things it will do and the convenience of it, YES, in great big capitals. The effects to be secured are as good and the conveniences greater; therefore, it must be better in many respects. For groups I have found it just as good by using a soft white screen between the light and the group. The light is screened on all subjects, but in groups it must be reduced more. This does not make it any slower than the skylight; therefore, that is not an objection.

FELIX RAYMER.

## ON THE DIFFERENCE IN INTENSITY OF DEVELOPMENT FOG ON EXPOSED AND UNEXPOSED DRY PLATES.

WHEN a gelatino-bromide plate, which has not been exposed to light, is treated with a developer it is always possible to produce a certain amount of so-called chemical fog; whilst a similar plate which has been normally exposed and developed under the same circumstances results in a negative perfectly free from fog. This fact, although frequently published, has not been hitherto, so far as we are aware, explained.

We have made a series of experiments with the object of discovering the cause of this phenomenon. These tests were carried out with extra-rapid gelatine plates, and we have attempted to

determine the influence exerted on fog by the following factors:—  
Time of exposure, duration of development, nature and composition of the developer, the combined effect of exposure and time of development.

We used the following normal diamidophenol developer:—  
Diamidophenol ..... 5 gms.  
Sodium sulphite anhydrous ..... 30 gms.  
Water ..... 1,000 ccs.

We developed unexposed, correctly exposed, over-exposed, and under-exposed plates in the same bath at a temperature of 65 deg. Fahr. for increasing time of from one to ten minutes. With the unexposed plates the chemical fog is practically nil with a duration of development of one minute, very distinct after two minutes, and increases very quickly with the duration of development. With the correctly exposed plates the fog was scarcely noticeable after about ten minutes' development. Under otherwise equal conditions the fog appears the more intense the less the exposure.

### The Influence of Temperature.

This test was repeated with the same developer, but at a temperature of 77 deg. Fahr. instead of 65 deg.

Drs. Mees and Sheppard state in their paper on the theory of photographic processes (PHOTOGRAPHIC JOURNAL, Aug., 1905, p. 296):—"It is usual in density measurements to subtract the so-called 'fog' from the total density. This is the density due to inherent fog in the plate, extraneous light, &c. Usually a separate reading is made of the so-called fog strip, but, owing to the differential nature of our instrument, the 'fog' reading was automatically subtracted, and taken from the same portion of emulsion as the exposure. But the formula  $D_{\text{net}} = D_{\text{total}} - D_{\text{fog}}$  shows that there is a theoretical error in assuming the fog in the exposed strip to be equal to that in the unexposed strip. For let  $A + B = C$  be total density of Ag Br, where  $A = \text{Ag Br changed by light}$ ,  $B = \text{Ag Br unchanged}$ . Then the fogging is  $(dD/dt) C = K(A + B)$  in fog strip, and equals  $(dD/dt) B = KB$  in unexposed film. Obviously, fog increases faster in unexposed film than in the exposed, "—EDS. "B.J."

The difference in the intensity of the fog which is observed in the plates of two and a half minutes increases in both cases with the duration of development, and only shows in favour of the exposed plate with a development of about ten minutes.

As before, the fog in the last case is more intense the less the exposure.

#### The Influence of the Nature of the Developer

The above experiments were repeated with two alkaline developers:—

1.—Hydroquinone .....	10 gms.
Sodium sulphite (anhydrous) .....	40 gms.
Sodium carbonate (anhydrous) .....	55 gms.
Water .....	1,000 ccs.
2.—Paramidophenol .....	20 gms.
Sodium sulphite (anhydrous) 25 per cent. sol. ....	1,000 ccs.
Caustic lithia .....	8 gms.

The results were the same as with diamidophenol.

When one considers the difference in the composition of the same developer, it will be noticed that in the first case the developer contains potassium bromide, and in greater quantities the more the plate was exposed and the longer the duration of development. The same result cannot occur in the second case, as the very faint reduction of the silver bromide is obviously limited to the formation of fog.

It may thus be assumed that the small intensity of the fog of the exposed plates in comparison with that of the unexposed, also the increase in the intensity of this fog with under-exposure can be ascribed simply to the retarding action of potassium bromide which is formed during development. In order to verify this hypothesis we have repeated the experiments with unexposed plates, and added to the developer as much potassium bromide as can be formed in the development of a normally exposed plate. We have thus determined that unexposed plates only give fog in amount equal to that which they would give if exposed, a fact which appears to support our hypothesis.

#### The Use of Stale Plates.

The above experiments were repeated with plates which had been made for a long time, and which, when unexposed, gave with short development, a fog which was distinctly visible to the naked eye. The fog which was obtained with exposed and unexposed plates, with and without addition of potassium bromide to the developer, did not markedly differ from the fog of the unexposed plates. The negative results must certainly be ascribed to changes in the plates, which were used for these last experiments, as the small quantity of sodium bromide formed during development was not enough to prevent the formation of the intense fog which such plates showed.

A. AND L. LUMIERE AND A. SEYEWETZ.

## COLOURED TONES BY THE TRAUBE IODIDE PROCESS.

[The brief notice which we accorded to the process newly discovered by Dr. Traube, whereby the formation of a silver iodide image is made the basis of a subsequent dye image, has following extract from which supplements the information in our paper, wherein he deals with the application of the process to Photography] Supplement

discovered by Dr. Traube, whereby the formation of a silver iodide image is made the basis of a subsequent dye image, has been further dealt with in our contemporary "Das Atelier," the issue of November 30, 1906. The full text of Dr. Traube's photographic three-colour printing, will appear in the "Colour Photography" Supplement for April 5.—Eds. "B. J."]

THE coloured silver iodide images can be used for purposes other than colour work. Transparencies for projection or window decorative purposes, and also paper prints, can be prepared by this process.

By means of the bleaching and dyeing solutions, which will shortly be introduced commercially under the name of "Diachrome" solutions, the conversion of the positives into coloured pictures can be effected in two operations. The composition of these solutions is such that the reactions take place in the most favourable way. The bleaching solution, which causes the conversion of the metallic silver into silver iodide, works very quickly, so that the process, even with the densest positives, is finished in a few minutes. As soon as the back of the plate appears perfectly white the excess of solution is washed out of the plate, an operation which only requires a few minutes. The subsequent staining takes a longer or shorter time, according to the density of the silver deposit. As soon as complete colouration through the silver iodide image has taken place, which is known by the absence of grey patches on the back of the plate, the process is finished, and one has only to remove the small quantity of dye which has stained the gelatine. As the composition of the dye bath is so chosen that the staining of the gelatine is limited to the utmost degree, the gelatine film will become perfectly clean after a short washing. If in individual cases, however, the dye should be retained by the gelatine, the addition of small quantities of acid, preferably acetic, to the washing water will considerably facilitate its removal.

For the decoration of windows, naturally those basic dyes which are most stable to light have been chosen. The four solutions give pictures in blue, green, red, and brown, which are very stable. The blue- and green-toned transparencies are especially stable, and some hung in a window which daily received the summer sun showed scarcely any change in appearance.

As the pictures were half covered with black paper the process was easily controlled. It should also be noted that "Diachrome" pictures, which, from prolonged exposure to bright and intense light, have become paler, will assume their original colour when again immersed in the dye bath. Besides the four dye solutions prepared for the above purpose there are three others which are not so stable, but which answer satisfactorily for all the requirements of projection work, and transparencies coloured blue-violet, reddish-violet, and light green can withstand for a very long time any projection lamp. As in this last case the characteristic colour of silver iodide, which looks brownish on the screen, plays an important part, the colours of the projected images differ from those of window transparencies. Above all, the shade of colour of the projected picture depends upon the density of the positive produced by development. If the image is very dense the colour tends to black, whilst soft, thin transparencies give almost the pure colour of the precipitated dye. The following are the colours obtained in projection:—"Diachrome blue" projects olive; green gives bronze; red gives reddish-brown; brown gives pure brown; green II. gives light green; reddish-violet gives red-violet; and blue-violet gives blue-violet.

As a general rule it is advisable to keep the positives for projection as delicate as possible; those for window decoration, on the other hand, should be very vigorous.

In order to make coloured prints on paper with the "Diachrome" solutions which possess every appearance of carbon prints, transparency films should be used. They are bleached and dyed as described above for plates. As the prints are produced by transfer of the gelatine film to paper, the transparency celluloid films prepared by Perutz of Munich should be used and printing done through the celluloid. This does not affect in any way the reproduction of the finest details. When the

coloured transparency films are finished, and they must be very thoroughly washed, and ought not to contain any excess of dye, the film and transfer paper should be brought into contact under water, as with ordinary carbon tissue, then carefully withdrawn

together to avoid air-bubbles, left for a short time between blotting paper under light pressure, and dried. When thoroughly dry the celluloid can be easily stripped from the picture.

DR. W. TRAUBE.

## PRACTICAL HINTS ON PHOTOGRAPHING HEAVY MACHINERY AND ENGINEERING WORK.

Of the many branches of photography perhaps none entail more serious thought and care to a photographer than is the case when he has to undertake the ever-varying requirements of large engineering and shipbuilding firms. Many subjects of this kind are not only large dimensions (shaftings being frequently as long as eighty feet), but are also, as in the case of heavy steel castings, of great weight, requiring the most powerful overhead cranes in manipulation. These modern electric cranes may at the outset be stated to confer an immense boon to a photographic operator, permitting, as they do, of his utilising them in placing his apparatus. The platform of the crane will serve in many cases; in others which have occurred in the writer's experience, a cage suspended from the crane and kept rigid by having drawn tight against its under surface four strong uprights from the cage), has been necessary.

### The Type of Camera.

Cameras of smaller dimensions than 15 x 12 inches are of no use this class of work, and, all told, perhaps this size is preferable for larger apparatus, for, in the event of the prints being required larger size than 15 x 12 negatives yield by direct printing, a good negative will easily produce bromide enlargements up to 6ft. or

As to the best form of camera to use, the climber which a photographer has to undertake make portability of the first importance. Still, there is a happy medium between the light and heavy, and I will now describe the alterations and attachments that were made to an ordinary front extension 15 x 12 camera, to make it especially suitable for this class of work.

The worst features in some patterns of large front extension cameras are the want of protection for the focussing screen, and the absence of side swings at the back, whilst in many instances the net upright carrying the lens is not held sufficiently rigid by the supporting rods. A side swing is particularly wanted in engineering work, where large marine engines for paper-making machines—to get two samples—have to be photographed as close as 15ft. from the end, and yet show detail along a 50ft. or 100ft. length.

### Adapting a Front Extension Camera.

On the other hand, a front extension camera has advantages, in respect of weight and bulk, over the old and more cumbersome tilting tail-board form, which, in confined situations, when using objectives of short focal lengths, makes sharp focussing a matter of difficulty by reason of straining the neck to get sufficiently close to the focussing glass. The thickness of a large front extension camera (say, 15 x 12 inches) when folded up is only 3½ inches, whilst a 12 x 10 of the tail-board pattern is nearly 6in. in thickness, when the former, weighing about 16½lbs., is fitted with a good handle to the top of the camera it is surprising how easily the same can be carried by one hand. This is most important when the operator has to climb ladders and cross stages. The writer therefore prefers a front extension, and has provided a side swing as follows:—In this form of camera the back is held by hinged brass plates on both sides of the base board, the brass plates being attached to the milled head screws passing into bushes deeply sunk into the base board. By merely unscrewing these the back bellows is released, and can be lifted bodily on to the brass runners on top of the base board, the flexibility of the bellows permitting the back of the camera to assume any desired position. To hold it firmly in position the milled heads are first unscrewed from the brass plates. Thin laths of wood are caused to bind the back of the camera to the proper amount of side swing has been secured and the final adjustment adjusted to the base board of the camera. The milled head screws will be found to fit exactly the forward bushes intended for

the use of short focus lenses. Having made fast the side of the camera nearest the lens by means of firmly screwing one of the thin laths to the base board of the camera by one of the milled heads and clamping the other end with the screw of the guy rod in the middle of the back, that side of the back is quite rigidly fixed, and then it is easy to press the other side requiring the longer focus into its position. When this is done the other lath is attached by means of the other screw in exactly the same manner. At one end of the lath it is advisable to bore one or two holes, to permit of the screw passing through them somewhat tightly into the bushes. These little laths are preferable to metal struts, such as brass or zinc, but, of course, either of the latter can be substituted if desired.

### A Ground Glass Protecting Board.

As regards protection for the ground glass, the writer's experience has taught him that it is better to dispense entirely with leather cases for such large cameras. Since adopting the following simple method of protecting the focussing screen he has never met with an accident. Provide a ¼in. board and cover one side with black velvet. The board must be slightly larger than the ground glass. At each of the bottom corners are attached two loops of cord, whilst at the top a large single loop or sling passes from corner to corner, just like hanging a picture. The bottom corner loops are merely slipped over each of the milled heads, found at the bottom of all cameras of this pattern; the top cord is then made of the exact length to allow the board to exactly cover the glass, and is held in position by passing it around the leather handle. The board when not in use is utilised for an important purpose, which I allude to below.

### A Practical Tripod Top.

The tripod is a matter of great importance in the work under consideration. What may be termed even a light 15 x 12 camera weighs as much as 17 lbs., and when to this is added the weight of one double back containing two plates, it will be found the tripod has to sustain a weight of about 24 lbs., which it has to do in various situations, ranging from the hard concrete floor to the loose freshly made-up ground.

The writer knows from experience, when working in such places as large foundries and forges, etc., where the floor is "tricky," how liable the camera is to sink during a long exposure unless special precautions are taken.

As a rule, a 12in. top is none too large for a 15 x 12 camera, which, in the most compact form, will measure 20in. x 17½in. when set up, but, of course, there is a limit to the span of the legs of the tripod, and, all told, perhaps a 12in. brass top is as practical a size as any. But to be used in its best form it should be enlarged in the following way (the plan the writer has employed, after many years' experience):—A couple of good cross-ended boards, 17in. long by 13in. broad, are hinged together, like the back of a printing frame. Through the underboard, nearly, but not quite, in the centre, a hole is bored sufficiently large to permit of a strong winged bolt being passed, the head of which is sunk flush with the board. This bolt (which should be 3in. in length) is inserted through the under-board and the stem passed through the screw hole (not screwed in) of the tripod top, and the boards then made fast with the winged nuts. By this arrangement the legs of the tripod can always be at any equal distances from each other, and whenever any tilting has to be done the hinged board can be used instead of tilting the tripod legs. The camera is easily fixed to the top board if desired by the camera screw, but usually it will be found that if the slides and their shutters are working sweetly (as they should do) it is not necessary to screw up the camera on the top board, for if a ¼in. ledge is run along the

hinged end of the board, the camera sits as steady as it would on a studio stand.

### Supporting the Tripod.

For this arrangement to be perfect the legs of the tripod must be very substantial, and possess some arrangement whereby when working in loose ground there is no liability to sink during a lengthy exposure. Probably the best, if, indeed, not the only perfect form, is the good old "professional" pattern—viz., six strong ash sticks without joints, hinged together at a distance of about 3in. from the bottom, to which are attached three well-pointed shods of not less than 3in. in length, well set into the bottom of the longer sticks. This is important, as a precaution against slipping. From the point where the two sticks (forming one leg) are hinged together to the point of the longest leg, is bound with stout copper wire until the metal shod is reached (just like a spinning-top is wound with string). This prevents any liability of the shod splitting the end of the stick, and is most effectual. Three inches is not too long for the shods, so as to provide for a good grip when carrying a weight of 25 lbs. in soft ground, and, as a further precaution against slipping and sinking, the writer invariably passes over the shods three 1in. discs of wood, each having a small hole bored out of the centre for the points of the shods to pass through; by this means both sinking and slipping are prevented.

There are many instances where the best tripod is none at all. A resourceful operator will often prefer to work from a box or other suitable support, such as planking on short trestles. A word of caution at this juncture, however, may not be out of place where work has to be done from high stagings, supported on tall trestles. In very many large engineering and boiler shops the old-fashioned wooden trestles are no longer met with. In their place are portable metal uprights, with a suitable solid base. These are more portable, and are often to be met with up to 30ft. in height. Two of these standards joined by stout planking across them are no doubt safe enough, but the writer's experience is that they do not afford as much stability as the old-fashioned wooden ones. However, a good rule to follow is, never allow any one to go on the staging when the plate is being exposed—even an assistant is liable to cause failure through movement. I know one very useful operator who always provides two stages, one for the camera and another to stand on himself during exposure.

T. NEWTON ARMSTRONG.

(To be continued.)

THE DATE of the volume of "The Photographic News," in which appeared the example of the "Dallastint Natural Grain" process was wrongly given, Mr. Dallas writes us, in his article of December 21 last, as 1868. The year was 1864.

DEATH OF MRS. ARTHUR C. BROOKES.—Many of our readers, we are sure, will join their sympathies to ours on hearing of the death, after a few days' illness, of the wife of Mr. Arthur C. Brookes, of Messrs. Marshall, Brookes, and Chalkley. Mr. Brookes's home life had been one of uninterrupted happiness for many years, and his loss must fall on him as a most severe shock.

DEATH OF GEORG. SCAMONI.—A St. Petersburg reader, Mr. C. T. Chesterman, writes us as follows:—"I beg to notify the death of my friend, Mr. Georg. Scamoni, in his 72nd year, after a short but painful illness. He was for thirty-seven years manager of the photographic department of the State paper manufactory in this city, but has been living in retirement for some years. He was honorary member of the Frankfort and Copenhagen Photographic Societies, also of the Imperial Russian Technical Society, and Cavalier of the Orders of St. Anne and St. Stanislaus, and recipient of several diplomas and prizes for exhibition and literary work."

ROYAL INSTITUTION OF GREAT BRITAIN.—The programme of forthcoming lectures at the Royal Institution of Great Britain includes several subjects of interest to photographers. Professor A. H. Church is to lecture on April 12 on "The Conservation of Historic Buildings and Frescoes," an address which will doubtless deal with the chemical aspects of this important question. On April 29 Mr. James Swinburne lectures on "New Illuminants." After Easter Mr. H. F. Newall delivers two lectures on "Spectroscopic Phenomena in Stars," and the three Tyndall lectures are to be given by Professor Sylvanus Thompson, on "Studies in Magnetism."

### MESSRS. JOHN J. GRIFFIN'S NEW PREMISES.

ALTHOUGH the occupancy by Messrs. John J. Griffin and Sons, Ltd., of the large building in Kingsway has been an accomplished fact for some months it was not until Wednesday last that the formal demonstration of their new enterprises took place. A numerous company then assembled to a press and private view, and had an opportunity of judging of the present magnitude of the firm's business.

It will be news to many people that the business of John J. Griffin and Sons was originally an offshoot from the publishing firm of Richard Griffin and Co. In 1836 a branch for the sale of chemical apparatus was added to the latter business, and in 1849 became an independent concern, the publishing house becoming the well-known firm of Charles Griffin and Co., Ltd. As long ago as the fifties

Illustration of Daguerreotype Outfit from a catalogue of Messrs Griffin, issued March, 1852.

the last century Messrs. Griffin were busy catering for photographers as witness their catalogues of apparatus for the Daguerreotype and other processes, one illustration from which, from a list dated March 1852, we reproduce.

From Baker Street, where it commenced, the firm eventually moved to Garrick Street, Covent Garden, thence to Sardinia Street, the premises vacated five months ago for the large and well-organised block, which is now occupied with the photographic and chemical branches of their business.

Messrs. Griffin have followed close on photographic progress—this is, when they have not themselves been the pioneers. When they offered the British public the now universal gaslight paper they

The New Demonstration Gallery.

embarked on a career of education and demonstration that has led them now to set apart a portion of their establishment for the special purpose of showing the photographic worker the proper use of his materials. Our second illustration shows one side of the demonstration gallery, where also exhibitions are to be held from time to time of pictorial work, which, as Messrs. Griffin solemnly promise, "is not beyond the understanding of the average amateur." For this relief, much thanks; another dose of "modern" photography would be too much.

On Wednesday the demonstration included oil printing,

Mr. G. E. H. Rawlins, the modern exponent of the process, and the inventor of its pictorial application. Mr. Rawlins showed how very easy, in the hands of a skilled worker, the process is, and his synthesis of pictures from a semi-visible image should be a stimulant to many to take up the use of the materials supplied by Messrs. Griffin.

A Corner of the Gallery.

Gaslight printing on Velox paper, the manipulation of "Goldona," Messrs. Griffin's self-toning paper, were also demonstrated, as were also the self-focussing "Autokon" enlarger, and the various types of hand and field cameras. In connection with these demonstrations we should say that one is given on the afternoon of every week-day, except Saturday, and that all are, of course, free to customers of the firm.

In addition to these entirely practical aids to the amateur worker, Messrs. Griffin are placing at their visitors' disposal a library of standard works on photography, and are also providing dark rooms or changing and developing plates.

In the "process" department of the firm was arranged a complete plant for the photo-engraver, with other apparatus for process work which Messrs. Griffin supply. One piece of apparatus was specially

A Demonstration Dark Room.

worthy of notice—namely, a hand engraving tool, worked by a small motor, by which light routing can be done, and small alterations in blocks or stereos made by printers on the machine. Space forbids us to refer at length to the very interesting chemical and chemical apparatus department of Messrs. Griffin, but enough has been said to show the well-considered steps taken by the firm to consolidate still more securely its position among leading houses of supply.

**PHOTOGRAPHY IN COURT.**—At the conclusion of the Kirk divorce case on Monday last Sir Gorell Barnes referred to attempts that had been made to obtain photographs in court during the hearing of this case. When in August last he stated that he would have no more sketching in court he meant to include photographing and all other methods of obtaining illustrations. He held a very strong opinion to the undesirability of directing special attention to cases in the divorce court by means of portraits taken either in or out of the court. He noticed with gratification that since the order made last August with regard to sketching, the Press, with but one or two exceptions, had acted upon it, and he believed those published had been due to a misapprehension of what he intended to convey.

### THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

THE annual meeting of the Professional Photographers' Association took place on Friday last, March 8, at the house of the Royal Photographic Society. On the previous evening a dinner of the committee and their friends was held at the Villa-Villa Restaurant, Mr. Martin Jacollette in the chair. Amongst those present were Messrs. Alfred Ellis, T. C. Turner, Frank Turner, Henry Spink, Lang Sims, A. Mackie, Thomas Birtles, Arthur Weston, H. E. Hull, P. E. Marshall, Henry J. Comley, R. Fellows Willson, and G. E. Brown (THE BRITISH JOURNAL OF PHOTOGRAPHY). A number of toasts were proposed, and the evening was interspersed with a

Mr. Henry C. Spink, elected President of the Professional Photographers' Association, March 8, 1907.

series of vocal efforts by members of the Association and their friends.

#### ELECTION OF PRESIDENT.

At the annual general meeting, the report of which will appear in our issue next week, Mr. Henry C. Spink, of Brighton, was elected President of the Association for the forthcoming year, which terminates in March, 1908. Mr. Spink has been a strong supporter of the association from an early stage in its history, and in the position of president may be expected to render to the Association all the aid possible from an experience acquired during a successful business career.

**INTERNATIONAL CHEMICAL COMPANY, LIMITED.**—Capital, £2,000, in £1 shares. To acquire the business carried on at Ravenswood Road, Balham, as the "International Chemical Company," to adopt an agreement with C. H. Whatley and H. J. Bedson (vendors), and to carry on the business of chemists, druggists, manufacturers of and dealers in pharmaceutical, chemical, industrial preparations and photographic requisites, etc. No initial public issue. W. W. Aspinall and C. H. Whalley are permanent directors and joint managers, subject to holding £500 shares each. Remuneration of managing directors, £150 each per annum. Registered office: 70, Ravenswood Road, Balham, S.W.

## Photo-Mechanical Notes.

### Reproductions of Copper Plates.

A PATENT (No. 9,796, 1906) has been taken out in this country by Ernesto Bianchi, 3, Via Po, Turin, Italy, for preparing negatives of musical matter (copper-plate engravings), which can be stored for any length of time, from which can be obtained, after any length of time, as many transfers as is required upon a stone or other lithographic surface.

To this end the copper plate, engraved with the design and duly corrected, is inked with a roller in the ordinary manner with any absolutely black printers' ink, of which the ingredients are finely ground and which is soft, but contains no varnishes; on the plate, inked in this manner, is placed a sheet of very adhesive printing paper made with finely ground pulp, and with a perfectly smooth calendered surface and not coated with gelatine (animal glue) and the whole is subjected to a suitable pressure. A sheet or negative proof is pulled therefrom, that is to say, a proof having a black ground and white design (lines, notes, words), similar to a photographic negative.

The ink should be such as to give the highest possible degree of opacity, so that the black ground transferred on to the sheet of paper may not be traversed in any manner by the ordinary rays of light. For the purpose of ensuring the opacity of the ground the printed surface can be covered with impalpable metal powder which adheres to the ink and forms an absolutely opaque skin, whilst the white parts remain transparent.

This heliographic matrix or negative of cheap and light paper will be found economical and can be very easily used and kept; therefore the chalcographic plates can be melted up and the metal thereof be utilised.

The heliographic matrix obtained by this process is sufficient to effect as many transfers as may be required on to stones, plates, or other lithographic surfaces.

The transfer of this heliographic matrix or negative having an opaque ground and transparent design on to a stone or plate can be effected in the following manner:—

Over the stone or over a suitable lithographic surface is spread a properly measured solution consisting of a mixture of 10 parts of albumen, 25 parts of water, and 0.10 parts of salt of chromium; then the plate is left to dry in a quite dark chamber; a skin, which is sensitive to light will cover the whole surface of the plate.

When the surface is dry the heliographic matrix or negative which has been described is spread over it: the whole is then exposed under suitable pressure to sunlight for a certain time: after having removed the matrix or negative (to be kept) the printed stone or lithographic plate is immersed in a bath of slightly acidulated water.

The salts of chromium mixed with organic substances and exposed to the light for a certain time become insoluble in acidulated water and the parts which have become insoluble will take the lithographic ink; it follows that the skin which covers the surface of the stone or lithographic plate when in contact with the acidulated water bath becomes dissolved at the parts which have not been subjected to the action of the light, these parts correspond to the opaque ground of the matrix, whilst the parts corresponding to the words, figures, etc., which are transparent in the negative, remain insoluble. If an ordinary lithographic roller is run over the plate the parts which remain insoluble, that is to say, which have been subjected to the action of the light, take the ink, whilst the other parts refuse it.

The transfer obtained by this process is very effective, and preferable to the transfers at present obtained by various other processes.

When the printing is finished everything remaining on the stone is wiped off, and the stone can be used as required. If another edition is called for it will be only necessary to obtain another transfer by means of the same heliographic matrix and the described process.

### Grain Relief Printing.

HERREN E. REICHOID and E. Felsing have obtained a German patent for a pigment mixture for grained relief printing. 200 gms. of hard gelatine are soaked in 1,000 ccs. of water, the gelatine then squeezed out, and after the application of fresh water, melted in water not above 100 deg. Fahr. Candy sugar 30 gms., ammonia 10 gms., car-

bolic acid 2 gms., any dye 20 gms., alcohol 5 gms., and glycerine 8 gms. are added and the mixture filtered. The raw paper is softened in hot water for half an hour, till air bubbles are no longer seen. It is then taken out of the bath with a sheet of glass and squeezed down. The four edges are then turned up to the height of 1 cm., so as to form a dish. Of the above-mentioned solution, about 0.15 ccs. are coated on every 10 sq. cm. and allowed, the paper stripped from the glass and dried.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been received between February 25 to March 2:—

CAMERA STANDS.—No. 4,795. Improvements in camera stands.

Thomas Percivale Woolfe, 55, Chancery Lane, London, E.C.

SHUTTERS.—No. 4,830. Improvements in curtain-shutters. R.

Haddan, for the Optische Anstalt C. P. Goerz, Aktiengesellschaft, Berlin.

FILMS.—No. 5,729. Improved holder for films or the like. Gay-

lord Logan, 7, Southampton Buildings, London E.C.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

COLOUR PHOTOGRAPHY.—No. 15,506, 1906. The invention is intended to obviate the great difficulty in printing photographs in colours, that the positive prints, by the operation of developing and fixing shrink to such a degree that it became impossible to produce colour printing blocks from the same negative.

"The process consists in printing the back of the sensitised photo-print paper in the corresponding colours from blocks prepared from the same negative. The picture is then printed and fixed on the face side in the ordinary way, and the paper rendered transparent, so as to show the colours on the face side, by any suitable means." John Wagner, 12, Beulah Hill, Upper Norwood, London, S.E.

FOLDING CAMERAS.—No. 9,305, 1906. The invention relates to cameras in which the lens board is connected with the camera back by means of a system of shear-levers and in which cords or equivalent means are provided for operating the levers in such a manner that the distance between the objective and the plane of the sensitised plate can be adjusted.

Fig. 1.

Fig. 2.

According to the present invention the endless wire, band, cord, chain, or other traction-device for operating the connecting levers is arranged so that it surrounds one of the two frames interconnected by the shear-levers, and is therefore, located in a plane approximately perpendicular to the lens axis. This arrangement results in a more compact construction and

safer operation, compared with an arrangement of the operating strips or traction devices in a plane parallel to the lens axis, the latter construction not forming an object of the invention. If several pairs of shears are used one member of each pair may be connected with such a band, so that by moving the latter all the shears are simultaneously operated. To increase the reliability of the action two parallel bands are preferably used, and one member of each pair of shears is connected to one of the bands, and the other member to the other band. In this case the two bands must be moved in opposite directions. This can be effected in a very simple manner by connecting each band with a rack and by causing the two racks to mesh with a toothed wheel arranged between them. The two traction devices being operated together may thus be considered the equivalent of a single traction device. Reginald Haddan, 31, Bedford Street, Strand, London, for the Optische Anstalt C. P. Goerz, Aktien-gesellschaft, Berlin-Friedenau.

**VELOPING BOX.**—No. 7,012, 1906. The invention consists of a chamber to receive plates or films carried (for exposure) in a "film envelope" of the kind described in Patent No. 10,097, 1904, and consisting of (1) an inner sheath in which the film is held, (2) an intermediate safety blind, and (3) an outer cover or case.

The inner sheath is provided with flanges on three of its sides, under which the film is held, and is furnished with a stop to retain it in its adapter when the outer case and the intermediate blind are withdrawn prior to exposure. The outer cover is provided with a strip, which overlaps the joint formed at the junction of the cover and the lower flange of the inner sheath when the envelope is closed.

Figs. 1 and 2 are two shallow trays which form the developing box when fitted one on the other. Fig. 3 is a sectional side view, on line X. X. Fig. 2, of the box supported in its trough, of which one side is removed for obvious reasons.

According to one plan of carrying out the invention, there is provided a shallow rectangular tray *a*, Fig. 2, of any suitable material, and of such dimensions as to receive the light-proof envelope containing the exposed film. The tray is provided with right-angle flanges *b b b* on three of its sides, the fourth side *c* being left plain. A recess is made at *d* to accommodate the retaining stop fixed to the inner sheath of the envelope when the latter is placed in the tray.

A cover is provided to fit accurately on the tray *a* so that the two parts combined form a shallow box open at one end. The trays may be either hinged, or held together by suitable clips, *g g* Fig. 1.

Fig. 1.

Fig. 2.

Fig. 3.

On the cover, and near the open end, is fixed a double spring light-trap *h h* which may conveniently consist of hard rolled metal coil, or spring-operated hinged flaps, the purpose of the same being to close the open end of box and yet allow the outer cover envelope *i* with its strip *i*<sup>1</sup> to pass through without admitting light when preparing the film for development. The spring light-traps extend the whole width of the developing box, and are so adjusted that the inner one opens and closes before the outer one, during the passage of the light strip. In Fig. 3 the

strip is shown at *i*<sup>1</sup> in the act of passing the outer spring trap, the lower or inner one being closed.

At the lower end of tray *a* there is a fluid way *a*<sup>1</sup>, into which the flange *a*<sup>2</sup> on the tray *f* enters, and admits of the developer and other fluids to flow in and out, at the same time preventing light from passing through.

The flanges of the tray *f* are slightly shallower than those of the tray *a*, so that the flange *a*<sup>2</sup> is suspended from the bottom surface of the fluid way *a*<sup>1</sup> when the parts are together, to allow free access to the various solutions. This condition is clearly shown at *k*, Fig. 3.

In a modification of the invention a rectangular box is furnished with a series of divisions, each of which contains a double spring light-trap at the end, the opposite end being left open for the insertion of the envelopes containing the exposed films. After filling, a cover provided with a sinuous fluid way is placed over the open end and the whole immersed in a suitable trough after the removal of the outer covers and the intermediate blinds, but we prefer to form the boxes as described above and place them *en bloc* in an upright trough of a size proportionate to the number of films to be developed.

In either plan of carrying out the invention the outer covers of envelopes project slightly through the light-traps to admit of their being pulled away from the inner sheath. William Albert Edwards, 66, Cassiott Road, Tooting, London, S.W., and Houghtons, Limited, 88 and 89, High Holborn London, W.C.

**CINEMATOGRAPHS.**—No. 22,429. The invention relates to a cinematograph projector, and describes the formation of a centering device, in which the centring plate is in the form of a stirrup, with a handle, carrying the actuating roller, that operates the film, at a point eccentric from the centre on which the moving stirrup-plate revolves, so as to set the film accurately to the luminous point and to the aperture, the actuating roller having a Maltese cross pressing upon a wheel on which a pin is fixed by which the actuating drum and the Maltese cross is caused to revolve through one quarter of a turn. R. W. James, for the Compagnie Générale de Phonographes, Cinematographes et Appareils de Precision, 5, Rue Richempanse, Paris.

**PROCESS FOR CONVERTING COBALT OXIDE IMAGES INTO MANGANIC OXIDE IMAGES.** Ger. Pat. 180,947. September 26, 1905.

The purpose of this invention is to convert pictures in cobaltic oxide into those which can be readily toned. This is effected by conversion of the cobalt images into such as consist of the same dyes as the toned manganese images. The original images may be obtained by a catalytic process, as, for instance, by bringing into contact a paper prepared with cobalt acetate with a negative treated in the well-known way with hydrogen peroxide, so that a green image of cobaltic oxide is formed. If such an image be treated with a 4 per cent. solution of manganese acetate, or other manganous salt, and sodium acetate, at normal temperatures, the green image will become brown. The amines with their derivatives and salts, such as aniline, naphthylamine, toluidine, etc., are especially useful for further toning. The conversion of the image into a manganese oxide compound can be combined with the dye toning, by adding a manganous salt to the toning bath. The following bath reacts very quickly with manganous compounds: 50 ccs. saturated solution ammonium chloride, 20 ccs. 10 per cent. solution chrome alum, 5 ccs. 20 per cent. solution aniline hydrochlorate, 10 ccs. 10 per cent. solution of citric acid, and 30 ccs. water. If to this bath a manganous salt is added, the cobalt images are very rapidly toned, as though composed of manganese compounds, Claims.—1. A process for the conversion of pictures of cobaltous oxide compounds into manganous compounds by treating the same with manganese acetate or other manganous salt in the presence of an alkaline acetate. 2. A process for toning pictures in cobaltous oxide compounds by conversion of the same into the manganese images, according to Claim 1, and then treating them with suitable dyes, such as the amines, their derivatives, and salts. 3. Method of carrying out Claims 1 and 2 by using a combined bath of manganese salts and the dye. 4. A dye-bath for the process in Claim 3, distinguished by the addition of a manganese salt.—Neue Photographische Gesellschaft, Steglitz, Berlin.

**PROCESS FOR THE CONVERSION OF SILVER IMAGES INTO THOSE OF THE HIGHER OXIDES OF MANGANESE, AS WELL AS TONING SILVER IMAGES.** Ger. Pat. 180,948. October 13, 1902. An addition to Patents No. 157,411, of August 23, 1903, and 161,406, 1903.

The object of this patent is the use of manganous salts instead of the manganic, which are very difficult to prepare, for replacing the silver with the aid of acids or acid salts. A positive or negative bromide print is immersed in a bath of potassium ferricyanide and a manganous salt, so that the manganous ferricyanide replaces the silver. The following baths are suitable:—1. 100 ccs. of 0.5 per cent. solution potassium ferricyanide, 20 ccs. 2 per cent. solution manganous sulphate, 15 ccs. 10 per cent. solution potassium bromide. 2. 100 ccs. 5 per cent. solution potassium ferricyanide, 20 ccs. 2 per cent. solution manganous sulphate. 3. 100 ccs. 0.5 per cent. solution potassium ferricyanide, 23 ccs. 2 per cent. manganous sulphate, 15 ccs. 10 per cent. solution potassium bromide, 5 ccs. normal hydrochloric acid. 4. 200 ccs. saturated solution manganous ferricyanide, 10 ccs. 10 per cent. solution potassium bromide. 5. 100 ccs. saturated solution manganous ferricyanide in 25 per cent. solution of sodium tartrate, 10 ccs. 10 per cent. solution of potassium bromide. The action of the baths may be accelerated by heat. The pictures thus obtained are treated as described in the principal patent with alkaline solutions of potassium ferricyanide, and the manganous pictures toned with suitable dyes. Solutions of cobaltous salts may also be used. Claims.—1. A process for the conversion of silver images into images of the higher oxides of manganese, according to Patent 157,411, but instead of the manganic salts and potassium ferricyanide there used, solutions of manganous salts and potassium ferricyanide, with or without addition of acids, are used. 2. A method of carrying out Claim 1 by the use of a solution of manganous ferricyanide. 3. A method of carrying out Claim 1 by the addition of substances which form complex manganous salts. 4. A process of toning silver images in which, according to Claims 1, 2, and 3, they are converted into manganous images, which can be then subsequently toned by suitable dyes. 5. A method of carrying out Claim 4, by colouring the manganous pictures with cobalt salts. 6. A bath for the conversion of silver images into those of the higher oxides of manganese, according to Claim 1, which contains manganous salts and potassium ferricyanide. 7. Method of making the bath claimed in 6, in which, instead of using a manganous salt and potassium ferricyanide, manganous ferricyanide is used. 8. Method of making the baths in Claims 6 and 7, in which substances are added which form complex manganous salts.—Neue Photographische Gesellschaft, Steglitz, Berlin.

### New Trade Names.

#### Photographing Cobwebs.

A dark background is a great convenience (writes Mr. T. Hudson, in "Photography," of March 12, recommending an early hour in the morning for the photography of cobwebs), but it is not easy at an early hour to find a companion who will hold it. It is, however, generally possible so to fix the camera that a dark bush or hillside will form a good background. This is essential. If a photograph is taken of a web with the lower half against a dark bush and the upper part against the sky, it will be found that the part backed by the sky is invisible.

A warm, still day, followed by a calm, cold night, are the ideal conditions for giving a heavy deposit of dew. A valley through

which a river flows is the best, though by no means the only place to find an abundance of subjects.

#### Multiple Portraits.

Just use a dark background (writes Mr. J. Peat Millar, in "The Amateur Photographer," of March 12), and have a dark cover over the table; that is all. You will see the idea—light dresses against a dark background. Nothing could be more simple. But the background must be dark, and is better if of a dark red colour. Art seating does very well, and the same will do for the table cover. Focus someone at each end of the table, also in the centre, so as to be sharp all over the plate. Then place the sitter in light clothes at one end of the table, and give an exposure only long enough to secure the light dress; then shift the sitter over to another part, and expose again. This can be repeated as often as there is room at the table.

Remember the plate remains in the camera all the time, and is exposed every time, and the same exposure must be given every time. Also bear in mind, if anything is to appear on the table, such as a cup and saucer and plate, only one of each must be used and moved along with the sitter. The idea is that the background, being dark, would require a long exposure to have any effect on the plate, say, ten seconds, and half a second might do for the sitter in the light dress (or even less), and if you expose four times on the sitter—that is, only two seconds altogether that the background has got—there is no much chance of veiling.

#### Wherein R.R. Exceeds Anastigmat.

To a large class of workers (writes Mr. John B. Hodges in the special "Spring" number of "Focus") whose photographic work is ostensibly of a pictorial character, the special properties of the R.R. should strongly appeal (and this particularly applies to the more rapid working types at apertures of from  $f/5$  to  $f/6$ , both on account of the soft delineation, and the power afforded of concentrating the definition on the principal object, whilst the remaining and less important parts of the picture are allowed to be more or less out of focus). In directing attention to this extremely valuable property of the "R.R.," the writer must not be understood as in any way desiring to depreciate the value of the anastigmat for general photographic purposes, for, if the analogy is permissible, the two types may be compared to the stage-coach and the modern locomotive, and although no doubt can exist as to the comparative value of the two methods of conveyance, yet there are still occasions when the stage-coach is infinitely to be preferred to the up-to-date locomotive.

#### FORTHCOMING EXHIBITIONS.

1907.

March 2 to 24: Marseilles Photographic Society.—Sec., M. Cullin, Rue St. Saviourin, 38, Marseilles.

March 7 to 16: Leicester and Leicestershire Photographic Society. Entries close February 16.—Sec., Lewis Ough, "Fernleigh," James' Road, Leicester.

March 14 to 16: Coventry Photographic Club. Entries close March 9.—Sec., T. J. Mercer, 6, Cope Street, Coventry.

March 22 to April 13: Northern Photographic Exhibition. Entries close March 8.—Sec., C. F. Inston, 25, South John Street, Liverpool.

March 23 to April 2.—Glasgow Southern Photographic Association. Entries close March 16.—Sec., Charles Young, 217, Oxford Road, Partick, Glasgow.

April 10 to 13: Ilkeston Arts Club, Photographic Section. Entries close March 27.—Sec., A. Smith, 11, Graham Street, Ilkeston.

April 17 to 19: Belfast Y.M.C.A.—Sec., J. W. Bushey, Y.M.C. Camera Club, Belfast.

April 25 to 27: Wallasey Amateur Photographic Society. Entries close April 10.—Sec., W. Hayes, 110, Brighton Street, Seacombe.

April 29 to May 14: Photographic Society of Ireland. Entries close April 22.—Sec., R. Benson, 35, Molesworth Street, Dublin.

May 6 to 10: Chemists' Trades.—Sec., A. Norman, "British and Colonial Druggist" Offices, 44, Bishopsgate Street Without, London, E.C.

## New Materials.

Specimens of Printing for Photographers. Produced by Walter Pearce and Co., St. George's Press, Brentford

Almost as essential nowadays as plates or camera, the modern album, booklet, or folder, drawing attention to a photographer's work, has risen in character immeasurably within the past few years. A less-favourably situated photographer has recognised that in the matter of his printing he need not be handicapped by his more fortunate rival. He has clothed his appeal in the best dress at his command, and has thus created in advance a favourable impression of himself and his methods in the minds of those who are persuaded to visit his studio. Messrs. Pearce, in laying themselves out to originate and design both the words and the style of a photographer's printed matter, have had the advantage of the resources of a practised printer of colour printers, as well as of the knowledge of a photographer's numerous specialties. As a result, we have to commend the appearance of their productions and the direct yet refined language employed. "In the Springtime," a little booklet that stimulates business at the present time of year, is daintily thorough as betrays its title, and is exactly the kind of leaflet to mark a photographer out as a cut above his fellows. Another booklet, "The Gift That Pleases," is equally attractive. At the prices which Messrs. Pearce undertake the execution of these booklets, collaboration with them should quickly pay a photographer with even slight additions to the production of distinctive work.

**HALIFAX WHITE BROMIDE PAPERS.**—The Halifax Photographic Company, 4, Victoria Terrace, Halifax, send us samples of the bromide papers (Glossy, Platino-Matt, Rough-Matt, Extra-Rough, and High-Cream), manufactured by them under the above name. Employing our customary developer of metol-hydroquinone, we were struck by the behaviour of the papers, the range of effects on the different brands being amply sufficient for all ordinary purposes.

## New Apparatus, &c.

**ALDIS "DUO" LENSES.**—Since the appearance last week of our report on the new "Duo" lenses of Messrs. Aldis we have received from the firm the circular of prices of the lenses now ready for the market. The circular also announces the issue of the Series II. "Duo" element to give a rapidity of  $f/12$  in conjunction with the element of the Aldis anastigmat. No. 2 is the only member of

series yet ready, and gives a focal length of  $11\frac{1}{2}$  inches. Its price is £10s. 6d., that of the Aldis, with iris mount, being £1 13s. The price of the No. 7 received last week, affording a focal length of 15 inches, at  $f/16.5$ , is £1 15s. 6d., the "Aldis" lens, with which it is used, being priced at £1 18s.. The facilities thus afforded for making the exchange from the front of the lens will be appreciated. The figure shows the exact size of the No. 2 with the "Duo" in place.

## Meetings of Societies.

Wrench. Rugby Photographic Society. "Photography" 1906 Prize Slides. Batley Photographic Society. "The Photographic Lens." C. P. Goerz.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held March 12. Mr. C. Welborne Piper in the chair.

A demonstration of the properties of dissolved acetylene was given by the Acetylene Illuminating Company, Ltd. The acetylene was used in solution in acetone, which, at the ordinary temperature and pressure, dissolved 25 times its volume of acetylene, and under increased pressure dissolved 25 volumes for each additional atmosphere. The solution was supplied in cylinders at 10 atmospheres pressure, so that the cylinder contained ten times its own volume of the gas. The demonstrators showed the use of the gas in ordinary lighting, and stated that, in consequence of the presence of the acetone, there was no carbonising in the burners, with the result that ordinary burners, such as the Bray 00000, might be used. The dissolved gas was very suitable for the oxy-acetylene light, and could

also be employed with a mantle. A vote of thanks was accorded to the demonstrators.

A paper on "The Isostigmat Lens, a new anastigmat lens that does not fulfil the Petzval condition," by Messrs. Horace C. and Conrad Beck, was read by the former. The authors pointed out that it had been stated by opticians that for a lens to be anastigmatic and at the same time to have a flat field, the so-called Petzval condition had to be fulfilled. That condition was that the sum of the focal powers of the individual lenses, multiplied by the reciprocals of their respective refractive impress, should be equal to zero. The authors' work, however, had led them to the conclusion that the fulfilment of this condition was not essential to producing anastigmatism over a flat field. The lens, which was the result of this work, was a 5-lens system, having the Petzval product mentioned above equal to .04 of an inch, the lenses being treated as infinitely thin in making the calculation. Contrary to expectation, the image at 35 deg. was only 1.50th of an inch from the plate instead of .48 inches, as it should be, according to the figure .04. The authors thought that the approximations employed in calculations in regard to the Petzval condition might account for errors in the conclusions drawn from it. In the case of the lens in question, the authors showed its ability to give freedom from anastigmatism over an angle of 70 deg.

In regard to oblique spherical aberration in the new construction, the authors showed the high correction obtained by means of microscopic images of a minute disc of light formed by the lens at angles of 5; 10, 15, etc., degrees (up to 35 deg.), on one side of the axis, showed the great differences between anastigmats in this respect. In some instances it was seen that the central correction was not perfect, a fact which depreciated a lens for such work as telephotography where the centre of the field was employed. This same freedom from oblique spherical aberration had a great influence on depth of focus in the margins of the field. If the correction was poor, the full depth was not obtained.

In the new construction the system of using lenses of low power and therefore of small errors had been adopted in preference to that of high powers and large errors. No component had a shorter focal length than that of the complete lens.

The authors then proceeded to discuss, with the aid of diagrams, the removal of the most important oblique aberrations from a lens, summing them up as astigmatism, symmetrical, and unsymmetrical oblique aberration, regular chromatic aberration, unequal magnifications of different coloured images, and distortion.

In reference to the commercial introduction of the lens, it was stated that two rapid ones would be placed on the market—viz., series working at  $f/5.8$  and  $f/7.7$  respectively. The single combinations with moderate stops could be used on the size of plate for which the whole lens was listed, and the foci were conveniently distributed, so that the new instrument acted as a three-focus lens. Thus in the  $7\frac{1}{2}$ -inch lens, the foci of the components were 11 inches and  $13\frac{1}{4}$  inches.

Mr. S. D. Chalmers said that it had been proved beyond all possibility of doubt that for a small angular field the Petzval condition must be fulfilled, and the Petzval condition would determine the value of the lens if there were no aberrations of a higher order. It was possible, from the value of the Petzval expression, to work out the figures of aberrations. Mr. Chalmers, from the theoretical standpoint, discussed the aberrations of the Isostigmat, and pointed out that, at the edge of the field—i.e., at an angle of 35 degrees—they would be one quarter what would be calculated from the differences named by the authors.

Mr. Cheshire referred to the original paper of Petzval, in which the limited expression employed by opticians was confined to a small area of field near to the axis of the lens—viz., to the vertex of the curvature.

Mr. F. J. Selby thought that the Petzval condition would hold good over such small angles as 15 or 20 degrees, and that the departures from truth after that would not be greater than the variations in other factors affecting the aberrations. He had calculated the differences of the "Isostigmat" curve from a flat surface at the various angles, and on comparison with the numbers given by Mr. Conrad Beck, in reply to the speaker, it appeared that the reduction was somewhat as stated by Mr. Chalmers.

Mr. Conrad Beck said that he had no intention of admitting that

the Petzval condition had been understood to apply over only a small angle. Opticians have talked of photographic lenses which complied with the Petzval condition, and these lenses embraced angles much greater than the range which was apparently granted to the Petzval condition by the previous speakers. If the Petzval condition applied only to angles of a few degrees, then it was of very little use to makers of photographic lenses who needed to design instruments of considerable angle. He believed the condition was advanced by Coddington as applying to a considerable angle, though there were passages in the early portion of Coddington's work which perhaps showed the existence of approximations in the calculations. The object of his brother and himself in the paper had been to call the attention of mathematicians to the fact, and he hoped that the result would be to provide opticians with a better working theory.

Mr. C. F. Lan-Lavis said that the Petzval condition was useful in producing a lens without aberrations of the first order, and then aberrations of the higher orders might be eliminated.

Mr. C. P. Butler, Mr. E. J. Wall, Mr. Gordon, and the chairman joined in the discussion, to which Mr. Horace Beck replied.

**SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.**—The organising committee of the South Suburban Photographic Society met last week, at 75, High Street, Lewisham, Mr. P. R. Salmon in the chair. After inspecting the new rooms the committee drafted the rules of the new society, and fixed the annual subscription at 5s., with an optional subscription of 1s. a year, in addition, for members who join the portfolio to be run in connection with the society.

A proposal to raise capital for initial expenses of furniture and apparatus, and for the cost of providing club facilities later on by a combination of members, to be registered as a friendly society, was adjourned for further discussion at the next meeting of the committee on the 20th inst. Amongst the letters read at the meeting was one from the vicar of Lewisham, suggesting that the Catford and Forest Hill Photographic Society (of which he is vice-president) and the South Suburban Society should be amalgamated in the common interest of the two societies. The secretary reported that he had replied to the effect that this was, and is, the object of the committee, and that it rested entirely with the Catford society to carry the suggestion into effect. The committee unanimously approved this reply.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—Meeting held March 7, Mr. Teape in the chair. Mr. Ernest Human lectured on "The Selection of Apparatus." Prefacing his remarks by some general advice on the choice of an instrument for a beginner, he advised a half-plate stand camera, with as good a lens as the purchaser could afford. Passing to hand cameras, the lecturer referred to the reflex type of instrument, the usefulness of which, he said, could not be too greatly extolled. The camera, however, must be of the highest possible make and workmanship, or things were liable to go wrong. Its good points were:—1st. It is an ideal hand camera, as one is enabled to focus the picture up to the very instant of exposure, the image being shown the right way up, but reversed left to right. This ensures sharp focus for every negative, and also that what is being aimed at is on the plate. The camera is usually of sufficiently long extension to allow of the single combination of the lens being used, is fitted with a front giving a fair amount of rise, and a reversing back, the shutter more often than not being of that most effective type, the focal-plane, the lenses, as they should be in such a camera, being usually of a leading maker. By the kindness of his employers, the City Sale and Exchange, 90-94, Fleet Street, E.C., Mr. Human was able to show some fifteen different models of cameras, illustrating his different points. The lecture was throughout highly appreciated, and a hearty vote of thanks was proposed by the chairman and seconded by Mr. E. T. Wright.

**SOUTHAMPTON CAMERA CLUB.**—The members of the above enjoyed on their last two evenings of meeting, the unusual circumstance of a divided lecture, a lecture the interest pertaining to which in the first half was so great that an even enhanced attendance greeted the second portion. The lecturer was Mr. W. R. Kay, one of the keenest workers in the club, and his subject was a description of the Swiss district of Valais, the first half being the itinerary, "From Visp to Zermatt," the second half being "Zermatt and Beyond." It is entirely impossible to follow the lecturer through his lecture, and

qually impossible to adequately refer to the magnificent collection of slides by which it is illustrated. Mr. Kay has in him that enthusiasm for the mountain which is leading him on through the more modest climbs to those of ever increasing difficulty, but his artistic temperament forbids him to return without those photographic spoils which give so much delight to the members of his own and the surrounding societies. In this lecture the differing characteristics of the Swiss scenery were finely displayed. The first journey showed the more gentle aspect of the lovely country, its beautiful valleys, its snug little hamlets, its rushing streams and foaming torrents, enough here and there came in a giant peak and glittering glacier. Beyond Zermatt, the Mecca of all Swiss tourists, the lecturer treated the sterner aspect of the country. Here were seen in panorama and in detail the mighty mountains, in all their lovely and their terrifying phases. The chaotic moraine, the icefall, and glacier, the condourous Serac, and the yawning crevasse, were all marvellously depicted in slide and in lecture. It was, however, the dreadful uttermost which proved the climax of the lecturer's skill, and while the tales of the dreadful tragedies, which have their history bound up with it, could not but impress the audience, the majesty and beauty of the lordly mountain grew upon those present in an overwhelming degree, as slide after slide of entrancing beauty was projected on the screen. Mr. Kay was most heartily thanked for his great effort, and the club members are extremely proud of the work that he has done; his series of slides must now be almost unique.

## Commercial & Legal Intelligence.

**PHOTOGRAPHS OF A GYMNASTIC SOCIETY.**—In the Belfast Recorder's court, last week, Mr. George Kennedy, photographer, 119, York Street, sued Wm. J. Young, 31, Oxford Street, to recover £2 19s., balance of account alleged to be due for photographs sold and delivered.

Plaintiff said defendant gave him an order in 1905 to go to the Whitehouse Gymnastic Club to take some photographs. He complied with the order, and supplied £4 9s. worth of photographs. Defendant gave him 30s. on account, but never paid the balance. On one occasion, when he asked him the reason why he did not pay him, defendant blamed witness for having sent postcards to some of his friends, but he never did so. He remembered the case being before the Court at the last sessions when his Honour threw out the suggestion that "defendant should collect the money," but witness had not received any money since.

Defendant denied that he had taken any personal responsibility in connection with the matter. He understood that plaintiff was to take the photographs as a speculation. Since his Honour made the suggestion that he should collect the money, he endeavoured to do so, and got 25s. 6d., which he was prepared to hand over. He thought the committee were liable for the amount.

Mr. Bulkinghorn, Whitehouse, a member of the committee of the gymnasium, gave evidence that the plaintiff came to Whitehouse and asked permission to take the photographs, and they said they did not object. He took the photographs two days afterwards, and it was arranged that they were to give the order for the number of copies when they saw the proof.

A decree for the full amount claimed was granted.

### NEW COMPANIES.

**SATINO, LIMITED.**—Capital, £500 in £1 shares. To acquire the photographic department of the business of the James S. Nunn Company, Limited, at 11, Queen Victoria Street, E.C. No initial public issue. Table "A" mainly applies. The first directors are: J. S. Nunn and F. M. Brooks. Registered office: 6, Church Road, Egate, E.C.

**HALLIWELL AND DAWSON, LIMITED.**—Capital £5,000 in £1 shares to carry on the business of chemists, druggists, drysalterers, oil and varnishmen, manufacturers of photographic, surgical, and scientific apparatus and materials, etc. No initial public issue. The number of directors is to be not less than two nor more than five. The first are: F. S. Halliwell, F. Dawson, and A. Constantine. Remuneration, £8 each per annum. Registered office: 6, Imperial Buildings, Le End, Birmingham.

**NEWMAN AND GUARDIA, LIMITED.**—Capital, £1,000, in £1 shares. To acquire the business carried on at 92, Shaftesbury Avenue, and

Pine Grove, Tollington Park, London, as "Newman and Guardia, Limited," to adopt an agreement with P. Mason, and to carry on the business of manufacturers of and dealers in scientific instruments, cameras, photographic lenses, and photographic apparatus materials and accessories of all kinds. No initial public issue. The number of directors is not to be less than two nor more than five. The first are:—A. S. Newman and J. W. Belsey. Qualification (except first directors), £100. Remuneration as fixed by the company.

## Dews and Notes.

**ADVERTISING PHOTOGRAPHY.**—From the Percie T. Edwards Illustrating Company, Thanet House, 231, Strand, London, W.C., we have received a mnemonic circular of the firm's work, which is such an excellent example of the photograph made for advertising purposes that we reproduce it herewith. Those who know Mr. Edwards will recognise him in the counsel addressing the Bench with obviously incisive eloquence, and it is a happy idea to associate himself in this way with the Law Courts, opposite to which his place of business is situated. The document, which can be seen in the counsel's bundle of papers, is removable—it is impos-

"M'LORD, I HOLD IN  
MY HAND THE STRONGEST  
EVIDENCE—"

sible to resist the temptation to examine it—and is found to contain a statement of the firm's offers to its customers in the following form:—

We make Illustrations for Commercial Purposes—Booklets, Catalogues, Show-Cards, and Magazine or Newspaper Advertisements. We make Photo-Studies from Life—one of the strongest and most direct methods of illustrating any advertisement.

We originate Ideas and put them into effective shape for advertisers. We photograph Catalogue Articles and retouch prints in such a manner as to show the selling points to their best advantage.

We make Technical Drawings for Engineers.

We model Designs in Clay for advertising purposes.

We also make Modelled Type Designs—an attractive style which has not yet been overdone.

We have alluded several times of late to advertising photography,

and have reproduced several examples of this branch of work from American sources. It is all the more gratifying, therefore, to mention the work done by Mr. Edwards in the heart of the London advertising world.

**SUNDAY TRADING.**—It is perfectly preposterous (says the *Globe*) that any village fanatic who chooses to do so can summon a local shopkeeper under a musty statute of Charles II., and can continue to do week after week until he grows tired of the pursuit, or is touched by a dim sense of the absurdity of the proceedings.

MR. CARL HENTSCHEL, the founder of the firm of photo-engravers of that name, has written a paper on "The necessity and advisability of limited liability companies being placed on the list of voters." It is evident, since this prominent City politician invited the public to take shares in his business, that he has been impressed with the importance of his body of shareholders. The grievance, however, is genuine; limited companies are heavily mulcted in rates and taxes, and at present they have no direct representation. For years past many chairmen, especially of companies owning large blocks of property, have agitated for voting power. Just imagine the huge sums paid by the leading railways throughout the United Kingdom, rates which certainly have become burdensome. As large taxpayers limited companies have a just claim to representation, but the difficulty is to find the practical remedy. "One company one vote" would not greatly affect the position, except in the City of London, and it would require miniature elections among each group of shareholders to decide how that vote should be cast.

## Correspondence.

\**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

### DEVELOPMENT WITH INSUFFICIENT REDUCER.

To the Editors.

Gentlemen,—In reference to the article by Messrs. Mees and Wratten on the above subject, the following note may be of interest.

Mr. Ernest Marriage wrote to me in April, 1905, that he had found a very good method of securing regularly graduated negatives of subjects with a great range of contrast. It was to over-expose the plate, then to commence development with a developer very weak in pyro, and strongly restrained by bromide. Development was slow, but as soon as the image was well out, the plate was washed, and the requisite printing density obtained by further development, with a strong unrestrained developer.

He asked me to examine the method quantitatively, and accordingly many experiments with measured strips were made which showed:

(a) That the higher densities were kept down owing to the deficiency of pyro in the developer.

(b) That owing to the large amount of bromide used, the apparent speed of the plate was reduced, and so the extra long exposure ensuring the shadow detail did no harm, while on washing out the bromide it rendered the further development easy.

(c) That on further development with the strong unrestrained developer, the increase of densities occurring in the period of correct exposure took place in a constant ratio.

To sum up, the method apparently lengthened the range of even gradation (increased the latitude of the plate), details in the shadows were well secured, and the high-lights not blocked up.—

Yours truly,

Arosa, Suisse.

W. B. FERGUSON.

### DAGUERRIAN PORTRAITURE.

To the Editors.

Gentlemen,—The portrait of Mr. Andrew Shanks, reproduced in your issue of March 8, is said to have been taken in or before

1843, but we are not told that the date was recorded till 1904. An interval of sixty-one years is a test of memory that few of us are likely to have to face, and that fewer still would encounter with success. Accepting, however, both the date and Mrs. Gardner's statement that her brother suggested to Daguerre the possibility of portraiture, and furnished him with his first sitter, it is, I think, probable that the portrait reproduced in your pages was not the result of that initial experiment. I base this opinion on the evidence afforded by the portrait itself. It is probable that, with an experience based only on the taking of buildings and landscapes, a good many portraits would be taken before the use of an artificial background of any kind came to be recognised as advisable. It is equally probable that many backgrounds would be tried and found capable of improvement before their evolution reached the landscape-with-the-pedestal-and-vase stage, of which Mr. Shanks' portrait is a good example.—I am, dear Sirs, yours faithfully,

Meadow Place, Wembley.

DONALD GUNN.

March 9, 1907.

### THE ACTION OF CHROMIC ACID UPON THE DEVELOPMENT OF THE LATENT IMAGE.

To the Editors.

Gentlemen,—In your article (p. 671) it would appear that there has been some misunderstanding with respect to the development of the papers and slides shown at the R.P.S. meeting. The subject of physical development was then only introduced to illustrate my statement, that "failure to obtain any development was no proof that the latent image had been destroyed."

All the rest of the papers and plates shown were developed in the ordinary manner with an alkaline developer. There was, however, a point of interest in the two physically developed slides which did not in any way relate to the subject. They were made to illustrate a paper on "The Two Latent Images (organic and inorganic) Development Before and After Fixing." (*Phot. Journ.*, 1898, p. 264.)

Both were exposed and fixed at the same time; one was at once developed with Wellington's Intensifier, whilst part of the other was developed in the same manner nine years later. I asked the society to keep both slides, as it might prove of interest to develop another portion twenty or thirty years hence. With respect to the point you have raised—that is, the effect of chromic acid, etc., upon a plate, fixed and physically developed—I may say that, so far, I have always been able to obtain development, but that the results are by no means the same as those obtained by direct development. I hope, however, that experiments in this direction may throw further light upon the constitution of the latent images.—Yours faithfully,

J. STERRY.

69, Elgin Crescent, Notting Hill, W

March 12, 1907.

### PROFITS ON POSTCARDS.

To the Editors.

Gentlemen,—I see Mr. Corkett did not reply to my query re reasonable price for the local photographer to take negatives for wholesale publisher.

Your correspondent "Postcard" is clearly in a unique position, and his experience can hardly be a guide for the great majority. He is, no doubt, right in not lowering prices to meet all. There will always be those who go in for the cheapest. Let them have it. Our aim should be to provide the best at a fair price. Photographs are not to be sold like sugar and tea.

The last clause but two in his letter, is, however, very hazy. He speaks of his professional friend "selling real photographic postcards from whole plates," and "exposing the cards in the camera, giving fifteen-minutes' exposure," and "pleased to get threepence each for them." Perhaps, Mr. Editor, you can interpret this, or perhaps you will prefer "Postcard" doing so.

It seems to me about on a level with another correspondent in your answers column last week who wanted "an apparatus for taking, developing, and fixing Daguerreotypes in one." I wondered whether he had ever seen a Daguerreotype. PROFESSIONAL.

# Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay. Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given. Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C. For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

## PHOTOGRAPHS REGISTERED:—

Desmond, Priory Street, Cardigan. Two Photographs of D. and J. Evans, the Welsh cancer healers.  
 Ven, 48, Broad Street, Newtown, Montgomeryshire. Photograph of the Newtown Baptist Ladies' Choir in Welsh costume.  
 Lugg, 3, The Arcade Okhampton, Devon. Photograph of Mr. S. Simmons.  
 Owen, 14, High street, Montrose. Photograph of Irish Street, Montrose, in snow. Photograph of a view of cutting, North British Railway, near Montrose, in snow. Photograph of a view of churchyard, Montrose, in snow.

## DESIGNS REGISTERED:—

Mills, Market Place, Ramsey, Isle of Man. Two Drawings of Crests of Ramsey Town, Isle of Man.

—From A. W. Isenthal and Co., Mortimer Street, London, W.  
 —The Schroeder lamp or the Ideal flash-lamp, either obtainable from Messrs. Houghtons, Fallowfield, or any dealer in London or the country.

ISH BELL.—We cannot say. Better address the manager, at 3,210, Locust Street, St. Louis, Mo., U.S.A.

—S. H. Fry, Frisian House, 5, Highbury Grove, Highbury, N.

ADA.—(1) Would it be advisable to go out to Canada without having a situation to go to? (2) If so, what part would you advise me, and when there where to make inquiries? I may say I am a good assistant operator-retoucher, and used to good-class work.—OSBORNE EDWARDS.

(1) Except that the general prospects of trade throughout the Dominion are very bright, we can give you no definite recommendation. If you are resourceful enough to turn your hand to other jobs which turn up, we say "go." (2) We cannot say. You might obtain some information from the "St. Louis and Canadian Photographer," 3,210, Locust Street, St. Louis, Mo., U.S.A.

ANCY.—(2) I believe there is a law to the effect that a person living in a house for a certain number of years without paying rent cannot be compelled to commence paying rent at the expiration of the term, nor can he be turned out—this would, of course, include studios. Should there be such a law, would you kindly extend your kindness and allow me to benefit by your knowledge of the British law? (3) I am wanting to obtain an appointment in India or thereabouts. Will you advise me as to the best course to take to obtain this, and if you think an advertisement or two in "B.J." would bring answers from India or representatives in England?—J. A. R.

(1) Against our rules. (2) A solicitor is better qualified to answer this query than we are. We have an idea, however, that the possession of real property for twenty years without acknowledgment of any previous ownership gives an absolute title to the property. But you had better consult a solicitor on the subject. (3) "The British Journal of Photography" circulates largely in India, and it is very probable that an advertisement or two in it may bring about what you desire.

STRATUM FOR CARBON TRANSPARENCIES.—Would you be so good as to advise me in your valuable columns as to the following? Is the coating of the glass for carbon transparency tissue, using the following formula, right? Gelatine, 1 oz.; water, 20 ozs.; bichromate potash, 1 oz. The emulsion is, of course, applied warm on a glass, washed in warm water, allowed to drain off slightly, and then another coating given, and then dried in a rack in the

light. I enclose transparency for your inspection.—S. LONGMAN.

The solution you are using is unnecessarily strong. The proportions usually employed are: Gelatine,  $\frac{3}{4}$  oz.; water, 20 ozs.; and just sufficient solution of bichromate of potash to give a golden sherry tint. Most workers apply the substratum to dry glass, after it has been thoroughly cleaned, but there is no reason why it should not be employed, as you have been doing, if the glass is warm at the time of coating.

COPYRIGHT.—(1) Has the owner of a non-copyright picture the right to give for reproduction a copyright photograph of that picture without the consent of the owner of the copyright photograph, the photograph being at the outset taken by permission of the owner of the picture for reproduction by himself? (2) In the event of a newspaper reproducing a non-copyright photograph do the proprietors become liable to the owner of the photograph if they sell copies of the newspaper containing the photograph after the latter is copyrighted, the newspaper having been printed before the registering of the photograph took place? Perhaps you would like to know the whole history of the matter, as it is a very interesting one. As brief as I can put it, it is as follows: I (say A) commission B to take a photograph for me of the picture belonging to C, C having given me permission to take this photograph of his non-copyright picture, in consideration of my publishing my photograph in the Press (this being to his interest, as it is of a certain scheme he is promoting). I impress on my agent B that on no account must any one have a copy of the photograph before I have sent mine off to the Press. In my absence from home C calls on B and gets two copies of the photograph taken for me, and gives one to D (a rival journalist), who reproduces the photograph without any arrangement with any one for so doing, and making my work entirely worthless. Over-tures are made to D's paper, with no effect, but after publication I copyright my photograph (the same one as used in D's paper). I afterwards buy copies of D's paper direct from his office, and also from newsagents. (3) Have I a case against the proprietors of D's paper? As I now stand, I have gone to all the trouble and expense of obtaining the photograph which D has used and got paid for, and my claim for payment is ignored.—J. S.

(1) Any one has a right to give a photograph, copyright or otherwise, to any one else. There is nothing in the Copyright Act against his doing so, but a person who receives the photograph has no right to multiply copies of it. Your agent, B, in the first instance, had no right to supply copies to C; but C, having got them, could give them to whomsoever he pleased. As the copyright was clearly yours, D had no right to reproduce, though if the copyright was not registered he could do so with impunity. (2 and 3) The photograph, having been registered, the owner of the copyright can take action for the delivery to him of the copies and can also restrain the further sale of copies by parties other than the actual producers of the copies. We would ask you if you are certain that the copy used by D is yours? C can allow any number of persons to photograph the picture and copyright is created in the work of each.

VARIOUS.—(1) What is the best way of mixing up the following acid fixer: Hypo, 16 ozs.; sulphite of soda,  $\frac{1}{2}$  oz.; alum,  $\frac{1}{2}$  oz.; acetic acid,  $1\frac{1}{2}$  ozs.? (2) What should you think would be the life of a gaslight print fixed in above bath? (3) Would potass carbonate, being used in developer instead of soda carbonate, affect the permanence? (4) Should you advise the toning of P.O.P.'s in sulphocyanide bath rapidly, or would five to ten minutes be correct? (5) What effect would an unripened bath have upon P.O.P.'s?—PERMANENCE.

(1) Dissolve the alum, acetic acid, and sulphite in one part of the water (you do not state the quantity of water in the formula, it should be 64 ozs.), the hypo in another, and mix the two solutions, adding the alum to the hypo, and not vice-versa. (2) The prints should last indefinitely if kept moving in the fixer for ten minutes. (3) No. (4) Ten minutes is an average time. (5) It reduces the strength of the print and tends to give double toning.

BROMIDES BY VIGNETTING.—(1) Can you kindly give me formula for toning bromide prints by copper and ferricyanide, one solution

which I like, as it gives varying shades? (2) Can you please give me the name of a good book that treats fully on this subject? (3) Will you also tell me how to vignette busts in the camera? What sort of vignetting board is put in front of lens to vignette off lower part of body in a bust, and how far away from lens should it be placed? Must vignetting board be same colour as background?—ANXIOUS.

(1) The copper formula given in the "Almanac" gives excellent results:—

A. Copper sulphate .....	60 grs.
Potass citrate (neutral) .....	240 grs.
Water .....	20 ozs.
B. Potass ferricyanide .....	50 grs.
Potass citrate (neutral) .....	260 grs.
Water .....	20 ozs.

To prepare the toning solution, use equal parts of A. and B. (2) "Toning Bromides," by C. Winthrop Somerville (Dawbarn and Ward, 1s.), or "Toning Bromide Prints," by Blake-Smith (Iliffe, 1s.). (2) A serrated mask is used in front of the lens. You can purchase the apparatus from any of the professional supply houses. See the announcements in our advertisement pages.

**LANTERN SLIDES.**—(1) Would you kindly give me a formula for making varnish for lantern transparencies? Also (2) what is the reason of the whitish appearance when looking down on to a lantern plate collodion process?—C. BARRY.

(1) Gum dammar, 250 grs.; benzole, 10 ozs. Apply by flowing over cold or by using a broad camel's hair brush. (2) Without seeing an example we cannot definitely locate the cause. It is, however, probably due to the silver bath being slightly out of order. The addition of a little more acetic acid to the developer will perhaps avoid the opalescence. If the veiling is but slight it will usually disappear on varnishing the slide with a spirit varnish, such as is used for negatives. With a spirit varnish the plate must be slightly warm before it is poured on, and made fairly hot afterwards. If this does not get you over the trouble send us an example of your failures.

**PORTRAIT.**—Will you kindly inform me where I can procure a picture of Mary Queen of Scots, reproduced in carbon or in any other process, and in sizes from 12 x 10?—A MAN OF KENT.

H. T. Leach, 3, Turl Street, High Street, Oxford; Miss Caswall Smith, 305, Oxford Street, W.; G. W. Wilson and Co., 2, St. Swithin Street, Aberdeen; John Stabb, Babbacombe Bay, Torquay; or Valentine and Sons, 32, Charing Cross, London, S.W. One or other of the above should be able to supply you.

**BLISTERS ON BROMIDES.**—I have been troubled by the formation of bubbles between the film and paper of bromide prints, when placed in the washing water after fixing. Paper supplied with hardened gelatine gave the same trouble as unhardened. Will you kindly tell me: (1) the cause, (2) a method of remedying (if possible), and (3) a method of avoiding this trouble.—A. W. HUTCHINGS.

This trouble arises in nearly every case either from marked differences between the temperature of the fixing bath and the washing water, or too strong a solution of hypo. The remedy for the first cause is obvious; that for the second is to immerse the prints after fixation in a 10 per cent. solution of common salt for about five or ten minutes and allow the washing water to mix gradually with the salt solution. Another remedy is to immerse the prints after fixation in a mixture of equal parts of methylated spirit and water, and then wash. Most probably a little attention to the temperatures will completely stop the trouble.

**W. L. KNIGHT.**—You do not state what paper you used, whether printed out or developed, nor what toning bath. We can only assume that you are toning with platinum and did not wash the prints before placing them in the hypo bath. We await sufficient information before saying more.

**A STUDIO QUERY.**—I shall be very much obliged if you can inform me how the very pleasing lighting, in which the head of a sitter is fully lighted and the drapery kept in quiet repose, is managed. I particularly refer to a set of portraits hanging outside the Palace Music Hall, which are exceedingly artistic and clever. I could not see any name of the photographer, but from my

knowledge and observation have no hesitation in thinking are unmistakably by H. Walter Barnett. Can you tell me such a light could be obtained in an ordinary studio, and mine, which you will see by the enclosed print? And also shape screens would be required to keep back the drapery. S. E.

1. There are several ways of producing the effect to which you refer. It is preferably done in the lighting by preventing full force of the light striking those parts of the figure to which you desire to subordinate; but the effect may be obtained modified, during development, by retouching, or in printing. We hope to print a short article on the matter in our next issue, which will give practical details. 2. We believe the studio is the largest in the South of England.

**E. P. C.**—Odd volumes of a journal are never of much value, they are usually wanted only by libraries, and it is a chance that you will meet with a purchaser for yours. We should say 2s. a volume would be a good market price for them. I might offer them to a second-hand bookseller, such as Sotheby's, Strand, London.

**H. EDWARDS.**—We will deal with your letter next week.

**R. D.**—The "Cusway" masks are stocked by the larger dealers, as Fallowfield and Houghtons. Vignetting masks of the type you name are a specialty also supplied by them. Salmon & Son, 52, Mattock Lane, Ealing, W., have a special article.

**A LEGAL QUERY.**—Would you be kind enough to give me information respecting the transaction as under? I sub-let a business to a tenant, who sub-lets, with my permission, to another tenant the same rent—viz., £60 per annum. My tenant has filed a petition, and the lease has been annulled. Now the present tenant refuses to pay more than £55 per annum. Can I claim possession of the premises, as he says he is no tenant of mine and he holds no lease, as the lease he had was annulled at the same time as mine was with my tenant, but I hold the original lease, and am answerable for the rent, etc.—G. STONE.

Without knowing the terms upon which you, already a landlord, granted the lease, and those under which you gave a sub-lease, I cannot advise you, more especially as the matter is complicated by the bankruptcy. The only advice any service that we can give is that you consult a solicitor, and show him copies of your lease and the sub-leases.

**ARTIFICIAL LIGHT.**—Can you tell me if a strong enough light cabinet full lengths could be obtained by fitting, say, twelve ordinary incandescent mantles in the acetylene apparatus illustrated in last year's "B.J. Almanac" (by Mr. Corke), instead of acetylene gas, and then connecting by a tube to an ordinary gas fitting? Would any special fitting for forcing the gas be required if it was only a five-light meter.—G. E.

The light would certainly do, but we expect you would find the exposure very long if it were used for full-length figures. To get even illumination it would have to be placed at a distance off. We should doubt if you could get sufficient light through a five-light meter to well supply a dozen burners as they were used under pressure. We should advise you to get a prospectus of Adamson's gaslight arrangement for portraits from Messrs. Still and Co., Charles Street, Hatton Garden, E.C.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the last portion of the paper.

## SUMMARY.

A paper read by the Brothers Beck, at the R.P.S., on "An Ignat which does not fulfil the Petzval Condition," has an important bearing upon the production of a cheap, efficient as well as a theoretical interest. Therefore, an understanding of the Petzval Condition (p. 211) is important.

The business, or the "bread and butter" side of photography, is given attention in articles on pp. 212 and 214.

A sulphite solution that is cheap and efficient and that will keep indefinitely needs no other recommendation. (P. 215.)

Full experiments which throw light upon the theory of the latent image are recorded on p. 216.

The preparation of the subject goes a long way towards securing success in many branches of photography. This is especially so in the case of the "Almanac," and the article on p. 217 is therefore especially interesting, noting by the photographer who may occasionally have to be "sitters."

A new method of arranging sitter, camera, and flash-light, to give good results at first attempt, or to repeat lightings once more, is given on p. 218.

Convention arrangements, promising a most enjoyable week, are summarised on p. 219.

Fallowfield Jubilee, a most unusual and interesting trade is described and illustrated on p. 220.

The Professional Photographers' Association presents a good case and deserves more support. (P. 221.)

## EX CATHEDRA.

### The Professional Photographers.

The report of the annual meeting of the Professional Photographers' Association, which we publish on another page, refers to general matters which deserve attention from every photographer desirous of seeing the increased prosperity of his profession. The association has been actively engaged during the year in negotiations with the Artistic Copyright Society in reference to the alterations in copyright law which are being promoted by the latter body. Photographers generally have to thank the P.P.A. for what it has done up to the present, though it must be regretted by everyone who can see the danger in which photographers' rights stand, that the majority of the profession should complacently watch those who are fighting for them without moving to their assistance.

### The P.P.A. and Canvassing Frauds.

We are glad to see, also, the heartless frauds which have been perpetrated in all parts of the country, in connection with the alleged free supply of enlargements, have been occupying the attention of the association. The business, however, is so managed that a charge of actual fraud is not easily brought against the canvassers, and, therefore, the association has moved in the direction of warning the public, through the local Press, of the essentially fraudulent nature of the offer made by the agents of the "free-portrait" firms. In one town—Northampton—the members of the association together advertised in the local press addressing a vital caution to the public. The association, we would point out, has drawn up a letter which can be addressed to the local Press in a member's district in the event of a visit from a gang of canvassers.

### Photo-graphers and the P.P.A.

We commend these and other matters in the report to the consideration of photographers outside the association. Every owner or manager of a studio who has held aloof from the association has the strongest reasons for seriously asking himself, why? The amount of the annual subscription (5s.) can be no obstacle, and we are at a loss to imagine that there can be individual antagonism towards a body which, throughout its six years' history, has shown itself both wise and energetic in protecting photographers' interests. In our judgment, nothing but a deficiency in the quality of *esprit de corps* among photographers is to blame for the disparity between the membership roll of the association and that to which its labours in advantaging photographers entitle it. If the association were in the hands of a less able committee, we should be reluctant to write of it as we have just done, but our hopes for its future are sustained by the support which

the inner body has rendered during the past year. Out of a committee of twenty, twelve of whom reside at a distance from London, the average attendance was 11 7-11.

\* \* \*

### The Photographic Convention.

The circular making a preliminary announcement of the Hereford meeting, to be held from July 15 to July 20, was issued last week, and, although only a very partial programme of the forthcoming proceedings, says sufficient to show that the twenty-second annual meeting of the Convention is to sustain the record of its predecessors. Among the papers will be the inaugural address by the president (Mr. Alfred Watkins), one by Dr. W. Scheffer on "Microscopical Researches on the Gelatine Film," and another by Mr. E. J. Humphery on "A New Aid to Pictorial Photography." Mr. Martin Duncan is to lecture on "The Romance of Insect Life," and the other features of the Convention, so we gather, will present the current aspects of photography in a complete and representative manner. Among the places to be visited in the Valley of the Wye are Ludlow and Ledbury, Weobley, Pembridge, and Goodrich. Yet Hereford itself provides almost sufficient opportunities for those intent on photography, and special facilities will be granted to members of the Convention for photographing in the Cathedral and other buildings.

\* \* \*

### Unseasonable Specimens.

On more than one occasion we have commented upon the way the majority of photographers neglect their showcases by exhibiting in them what may be termed out-of-season specimens. We have been forcibly reminded of this as, during the past few days, we have stopped to "take stock" of the specimens shown in the showcases of a dozen or more photographers in different parts of London. In all of them, with one or two exceptions, the whole of the portraits shown were taken in spring or summer attire. In the one or two exceptions, it may be mentioned that the portraits had evidently been taken a long time ago, for the costumes were much out of date. If photographers were to change their specimens with the seasons their showcases would prove far more attractive than, as a rule, they are, and consequently bring in more business. No draper would think of filling his windows with a show of summer fabrics during the winter months; he only shows those suitable for the season, whichever it may be. But photographers appear to take no heed of seasons. In winter they show specimens in the lightest summer attire, or, may be, in summer those in heavy winter costumes; in either case they look little less than ludicrously out of place. Now, ladies clad in winter costumes, with heavy furs, make most attractive pictures, yet these seem to be conspicuous by their absence in the showcases of the majority of photographers at the present time—the season they should be shown.

\* \* \*

### Defacing Proofs.

A Canadian reader of "The British Journal of Photography" endorses the principle of disfiguring proofs sent to customers in such a way that they cannot be used as originals for copies, or in other ways utilised by a customer who has no intention of paying for them. In preference to the perforating stamp which we suggested he writes "with a copying pencil the number of the negative near the face on each proof sent out. If any one attempts to tone the print he will speedily learn the peculiar properties of copying ink pencil, and the print is not likely to be very acceptable to the customer." It may be well to utter a word of caution as to the use of copying ink pencils in a studio or printing room. Any dust from them will be a very

likely cause of spots on prints, and therefore a rule should be made to keep the leads in holders, and never to sharpen the points.

\* \* \*

### Burners for Acetylene.

In the course of the meeting of the Acetylene Association, held a week or two ago, a paper was read by Mr. Arthur Bray on the construction of burners in which acetylene can be conveniently burnt. The ordinary burner, as Mr. Bray pointed out, suffers from several disabilities when it is employed for acetylene. The gas cannot be turned down to a pin-point, and the burner chokes or carbonises. Mr. Bray's firm had devised a burner which could be turned down low owing to an open superstructure erected over the tip proper. When the flame is turned on full, the superstructure is not in action. But when the flame is turned down to a small jet, what in the former type of burner would have been a small, luminous flame, is expanded by the superstructure, which expansion allows the surrounding atmosphere to come in contact and combine with the larger area of the flame, which renders it practically non-luminous, more especially that part of the flame which comes in contact with the vital parts of the burner tip proper, thus preventing the deposit of carbon. As regards carbonising, the lecturer's opinion was that it arose, in the case of air-injecting burners, from some slight obstruction at the point where the gas entered the minute gas passage that is to say, the underneath side of the tip. This obstruction checks the speed of the gas jet and prevents taking a sufficient quantity of air into the mixing tube, with the result that improper combustion causes deposit of carbon. Mr. Bray's experience that in the majority of cases the obstruction arose from impurities in the gas due to faulty generation, confirms the statement of the Acetylene Illuminating Company, reported in our last issue, that in the case of the dissolved gas there is no trouble from carbonising.

\* \* \*

### Some Old Literature.

An exploration around some London secondhand bookshops brought us to Wheldon and Co., Great Queen Street, where a valuable stock of old books of photographic interest was unearthed. Hunt's "Photography," Monckhoven's "Photography" and Barreswil and Devanne's "Chemistry of Photography" (1854) were in the list, but the optical books available were more particularly remarkable. These included Monckhoven's "Photographic Optics," and Brewster's "Stereoscope," and the following valuable series which we place in order of dates:—Newton's "Opticks," 1704; Smith's "Opticks," 1738; Wood's "Optics," 1818, and Coddington's "Optics," 1825. Of these four, Newton is, perhaps, of least practical value, though its historical interest is considerable. Coddington is scarce, and still of great value, so much so that many would like to see it reprinted. It is styled "An Elementary Treatise," but is very mathematical, and the greater part of it is probably quite beyond the comprehension of many people. So much has lately been said of this book in "The Photographic Journal" and elsewhere, that many are no doubt desirous of obtaining it; it may therefore be as well to point out that though it is invaluable to serious students it is of little use to most mathematical readers. Further, it is not in any case an easy book to read, for there are numerous misprints in the formulae which have to be checked by the reader, and the geometrical expositions are very much involved. It does not appear to us advisable to reprint this book as it stands but rather to rewrite it, eliminating the misprints, revising the Euclid, which in some cases is very bad Euclid, and enlarging the diagrams, which are all too small. The author himself apologises for the diagrams, and suggests

that readers should copy them on a larger scale, and so this much-needed alteration is quite justifiable. The two other books we have mentioned are referred to (amongst others) by Coddington, who states that his own book "is to be considered as a compilation rather than an original production," and he owns special indebtedness to Wood's "Optics."

#### Smith's "Optics" and Wood's "Optics."

These two books are less well known than the others we have mentioned, but their interest is quite remarkable. The first one, by Dr. Robert Smith, LL.D., is a colossal work compared to modern text-books, as it is four books and makes two large quarto volumes. It is especially notable for its thoroughness, as it covers practically the whole ground of optics, from popular, mathematical, mechanical, and philosophical standpoints. It is most fully and perfectly illustrated, and throughout shows the great knowledge of the author, who was, if anything, rather in advance of his time. The book finishes with a long essay by Dr. James Jurin upon "Distinct and distinct Vision," and the subject of vision is treated generally throughout the whole work in a remarkably apt fashion. Indeed, the photographic interest of the book is mainly in the section devoted to binocular vision, and reference to some of the interesting experiments described will be found in the "B. J. Almanac" for 1905, page 874. In an article by Dr. von Rohr, Wood's "Optics" was published much later, there being a difference of eighty years between the editions we are referring to, and it is a much smaller and more easily digested book. As before stated, Coddington found it of great value, but it is a remarkable fact that in his book he has apparently ignored one of the most important features. Dr. Wood treats not only of thin lenses, but also of thick ones, and the case of the latter he makes use of points which he calls "focal centres," which correspond to the points we now style "principal points" or "nodes." He measures the focal length of a thin lens from the optical centre, and that of a thick lens from one of the two focal centres, that is from the "node of emission." If we remember that this was a Cambridge text-book in 1818 it is most remarkable that this important conception of focal centres or nodes should have been ignored in later books. It seems to have been quite neglected, until the elaboration of the Gauss Theory, which theory again had a hard and long struggle for recognition. Only last year (1906) a somewhat important text-book was published, which completely ignored the theory of thick lenses. This was not a very creditable production, even if we allow for the obvious fact that it is a book intended to get university students through examinations, and that for such purposes it is only necessary to understand hypothetical thin lenses that cannot exist, real lenses being of no importance so far as examinations are concerned.

THE GERMAN PHOTOGRAPHERS' UNION is to hold its thirty-sixth meeting this year in Bremen, from August 26 to 30, favoured with co-operation of the Bremen Union of Professional Photographers and the Bremen Photographic Society. The Mayor of Bremen, Dr. Reuss, has accepted the honorary presidency. The place appointed for the sittings of the Union is the Parkhaus. An exhibition, which is usual to be connected with the meeting, will be open to the public till September 15. The North German Lloyd has extended its hospitality to this occasion, inviting the members, on August 29, to visit the works of the Bremerhaven docks and harbour as well as to express steamer "Kronprinzessin Cecilie," and afterwards to go far as Rotesand Lighthouse on board the steamer "Vorwärts," taking at the same time of an entertainment to be offered by the Lloyd Company. Persons interested either in the meeting or the exhibition will receive detailed information on applying to the president of the Local Committee, Mr. Willy Dose, Photographer, am Allee 117, Bremen, or to the President of the German Photographers' Union, Mr. Karl Schwieler, Weimar.

#### THE CORRECTION OF LENSES AND THE PETZVAL CONDITION.

THE paper on "A New Anastigmat that does not Fulfil the Petzval Condition," given by Messrs. Horace C. and Conrad Beck at the R.P.S. last week, led to a very technical discussion on the Petzval condition, which, no doubt, many of the audience failed to understand. A brief description of what is meant in optics by a "condition" may therefore be of interest, and, perhaps, of some service to those who wish to study Messrs. Beck's paper when the full text appears.

The correction of a lens is attempted in accordance with principles founded on a close mathematical analysis of the defects observed with uncorrected lenses. Such an analysis reveals the presence of a number of separate aberrations, each of which can be measured and described in terms of known quantities, such as curvatures of surfaces, density of material, distance of object, focal lengths of lenses, etc., etc. In this way a definite mathematical value can be assigned to an aberration, which value takes the form of a complex algebraical expression, including quantities that can be varied more or less at the will of the optician. It must be fairly obvious that if the optician can so vary the quantities as to make the complete expression equal to zero, then the aberration must vanish, and this is practically what he endeavours to do.

The requirements of photography as regards lenses are somewhat comprehensive, hence the number of possible aberrations is very considerable. The general principles of correction can, however, be very fairly understood if we consider only the five aberrations that are allowed for in Von Seidel's five conditions. These aberrations are central or axial—spherical aberration, coma, astigmatism, curvature of field, and distortion—and they must be considered exactly in this order.

The simplest of these aberrations is the first, and its measure in terms of known quantities (as previously described) may be denoted by the symbol  $S_1$ . If the aberration is absent,  $S_1$  must equal zero, and the equation  $S_1=0$  is the first Von Seidel condition, sometimes known as the Euler condition. This first condition being fulfilled, the measure of the second aberration, coma, can be represented by the symbol  $S_2$ , and this also must equal zero if the coma is to be eliminated.  $S_2=0$  is, therefore, the second Von Seidel condition, and it agrees with what is sometimes called Fraunhofer's condition, and sometimes Abbé's sine condition. To render the correction of coma possible this second condition must be fulfilled, but to effect the correction the first condition must also be observed. This interdependence of the various conditions is an important feature that is often overlooked.

The third aberration is astigmatism, and the Von Seidel condition is that a certain value,  $S_3$ , shall equal zero. When this is the case, and  $S_1$  and  $S_2$  also equal zero—i.e., when all of the first three conditions are fulfilled—the lens is free from astigmatism. If a fourth condition—viz.,  $S_4=0$ —be also fulfilled, then curvature of the field is corrected, and this fourth condition is the much-talked-of Petzval condition. The fifth condition is that a certain other sum,  $S_5$ , must equal zero if distortion is to be removed. This is often called the tangent condition. If all five conditions are fulfilled, then the lens is comparatively free from the five aberrations mentioned, but it is still subject to chromatic aberration, for the cure of which other conditions must be observed. It may be noted that there are difficulties in the way of applying all the required corrections simultaneously. For example, condition 5 alone will not completely cure distortion unless condition 1 applies to the pupils of the lens as well as to the object and image foci, and this double appli-

cation of condition 1 is more or less compatible with the fulfilment of condition 2 or the sine condition. Further, this latter condition is also antagonistic to the attainment of maximum depth, which requires the fulfilment of a quite different condition. At the best the result is a matter of compromise between different degrees of correction, while the actual manufacture of a lens requires a great deal of rule-of-thumb work in the way of tentative modifications. The mathematical calculations cannot be carried so far as to enable one to write an exact prescription for a lens that will do all that the photographer requires of it.

It should be clearly understood that the majority of the so-called conditions, including the Petzval condition in particular, are not absolutely corrective, but rather permissive conditions. That is to say, if the Petzval condition is fulfilled, it is possible to attain a flat field, but the actual attainment of that flat field depends upon the fulfilment of certain other precedent conditions.

The Petzval condition, stated briefly, is this: With combination of a positive and a negative lens a flat field can be attained if the focal lengths of the two lenses are inversely proportional to their refractive indices. If chromatic aberration is to be cured, then the focal lengths must be in the same ratio as their dispersive powers. It therefore follows that if both aberrations are to be corrected the refractive indices must vary inversely with the dispersive powers. This condition could not be realized even approximately with the old types of crown and flint glass, and owing to the importance of the chromatic correction, the Petzval condition could not be practically applied before the introduction of Jena glass.

Those who wish to make further study of the various conditions of correction will find the subject very fully treated in Prof. Sylvanus Thompson's translation "Lummer's Optics," and in Mr. Dennis Taylor's "System of Applied Optics."

## BUSINESS METHODS IN THE STUDIO.

## II.

LAST week's notes having shown the methods in which the general accounts are kept, it now remains to describe the private ledger, the book in which the various figures are brought together, and the results of the year's trading arrived at.

Perhaps the simplest way in which to do this will be to give Mr. Darkslyde's accounts in full for one year, and this is done in Fig. 4. A few observations may well be added.

### Profits and Drawings.

The capital account is the record of the value of the business itself. It increases or decreases each year by the amount

of the balance, which is transferred from the profit and loss account. Be it noted, by the balance which, as a reference to the latter account will show, is arrived at after Mr. Darnley's own drawings from the business have been reckoned. A business in which the proprietor is drawing £150 when profits are £180 per annum, is in a better state than one in which £220 is being drawn on profits of £200. This distinction between profits and drawings is very important, alike to the beginner and to the proprietor of the old-established business which, as is only too frequently the case, is on the decline. Unless some such system of accounts as is here

lined is kept, there is always the danger of overdrawing—once any business man does that, he is only accelerating own downfall.

Apparatus Account.

This account covers all the apparatus at the time of the stocktaking. Any purchases made afterwards are not entered under this heading, but to another account called Apparatus Renewals, which, it will be seen, is included in the profit and loss account as an expense. This is not quite in accordance with the usual accounting methods, but most studio apparatus depreciates in value so quickly that if the first valuation be allowed to stand from year to year, the value of the new backgrounds, lenses, etc., bought each year in the average studio will just about offset the depreciation. Bad debts account represents amounts that are written off the sitters' ledger as being beyond any expectation of payment.

The other accounts are the monthly totals from the day book cash book. Referring to the latter again as shown in the last week, the stocktaking accounts column contains payment of the accounts due to the various creditors at the time of stocktaking, the £148 in the balance-sheet, January 1, 1905, and the £155 in that of January 1, 1906. The

various items making up these amounts being charged to their respective accounts before they are closed, it will, of course, not be right to dissect them again at the time they are paid; hence the special column for stocktaking accounts.

Income-tax Assessments.

It may be mentioned that the profit and loss account as here shown furnishes the information required by the income-tax authorities when an appeal is made against an assessment. In assessing, if there be any mistake at all, it is unlikely to be in favour of the taxpayer, and therefore it is as well to be prepared to resist any over assessment by appealing within the time allowed. In the accounts shown, Mr. Darkslyde will not, of course, pay on the £250; he will fill in the exemption claim for £160 which is allowed on incomes under £700 per annum, while he may, if he wish, show the last three years' accounts, and pay on the average of the three. Thus, supposing that the three years' profits have amounted to £180, £200, and £250 respectively, the average, after deducting the yearly exemption of £160, is £50, on which amount he can appeal to be assessed instead of on the £290.

These notes will be brought to a conclusion next week by a few hints on the conduct of business between the photographer and the wholesaler.

S. E. KAYE.

## BREAD AND BUTTER SIDE OF PHOTOGRAPHY.

[The importance of the consideration by photographers of business details was the dominant note in the following address by Mr. L. D. Hicks, at the sixth annual convention of the Photographers' Association of the Pacific Northwest, for the text of which we are indebted to "Camera Craft." The address should confirm our professional readers in adopting a strict system of book-keeping, such as that advocated by a contributor on another page. —Eds. "B.J."]

An important subject this, for experience has taught me that photographers possess hearty appetites and that it requires much bread and butter to satisfy them. Robin Hood's friends were fond of a song which ran: "It takes nine tailors to make a man." We of the camera fraternity can truly reverse this song and sing: It takes nine men to make a photographer.

If the fairies could roll into one human form a diplomat, a politician, a chemist, a mechanic, a draughtsman, a financier, an expert salesman, a shrewd, level-headed modern business man, and an artist, the result would prove to be a remarkable and perfect photographer; one whose stock of bread and butter would accumulate to a degree that would start the Rockefeller and Morgans in the direction of the photographic stock house. We haven't any fairies, so which of these nine men shall we choose as our pattern? Give me the diplomat every time. It may be the reception-room lady, or in our smaller cities the proprietor himself, but, no matter who it is, the one who receives your prospective sitter, shows him his proofs and takes his money, surely must be more or less of a diplomat or there will not be much bread and butter.

All photographers are artists; some of them are realists, some impressionists, and many of them are just naturally poor artists; but that is equally true in the great art world that lies outside the photographic field. The poor ones will improve, or quit, so don't worry about them. The others are coming closer together every day. The impressionists' fuzzy-types grow less fuzzy; the realists' wirytypes grow less wiry, and the result gives the world a product that is a portrait and a picture all in one. This helps to spread the butter. But the bread must still come from the reception-room.

### A Lesson from the Manufacturer.

The photographer is a professional man, but he is also a wholesale and retail dealer in pictures. Do you run your studio on a business basis? Not many of you, I fear. You send to the dry plate manufacturer for a case of plates, he glances at your order and knows to a fraction of a cent not only what the cost of producing that box of plates was, but what each item that goes to make up the whole cost, even down to the labels on the boxes, and he can tell you the exact amount of his profit on that sale. You were by no means a stranger to him when your order arrived, for his card index system had long since claimed your address, and in all probability the little square of cardboard will tell him many other things; how long you have used his plates, for instance, and, incidentally, how much bread and butter you possess. Had you failed to send that order in when you did, doubtless a notice would have come to you in a short space of time from this same source, asking why your orders had dropped off, or, better still, the thirsty and travel-worn demonstrator would have called upon you and extolled the mighty virtues of this same dry plate. There's nothing strange about all this; it is simply a modern business house following the even tenor of its way.

### "Photographers Don't Keep Books."

Now suppose we reverse the case. We have a call from the factory man. He orders a dozen pictures; we deliver the goods, take his money, and—well I guess that's all. Do we know how much net profit there was in the sale for us?

Probably not. Do we know exactly what the material that went into that dozen pictures cost? I'm afraid not. And our factory friend hadn't voluntarily come for the sitting would we have gone after him either by letter or in person? And, if he doesn't come back next year, will we stir him up? Maybe. But not all of us, I'm afraid. Let me give you a secret that I heard back East: They say that "some" photographers don't keep books." How in the world can they tell where next month's bread and butter is coming from? The happy-go-lucky fellow with a few dollars in his pocket and a stock bill of unknown dimensions hanging off his head may be a photographer, but he is certainly not a business man.

A Philadelphia publication recently printed a story, which if it did not happen to be new, is one that most of us can take home to ourselves. An Episcopal bishop, while visiting in the country, heard that a certain farmer had long sung the praises of that creed and boasted that he was a mighty good Episcopalian. Naturally this pleased the bishop, and upon meeting the farmer he asked: "Who brought you into our church? Who confirmed you?" "Who what?" inquired the farmer. "I don't know what you're talking about, but this is how it happened: I was in New Orleans on Sunday and went to church, as I didn't have anything to do. While I was there all the folks in the congregation got up and said: 'We have left undone those things which we should have done, and have done those things which we should not have done.' Well, sir, that fitted me very exactly. I asked the man that sat next to me what kind of a church that was, and he said Episcopal, and I've been a good Episcopalian ever since." I wonder what percentage the membership of this Association this cap fits. Now we do some of these things that we should do and have left undone.

### An Index of Customers.

First, we want to install a simple and practical system of keeping a clear record of our business. This isn't going to cost very much. For one dollar and twenty-five cents we can buy a substantial box, black cloth covered and fitted with a good follow block. This box contains 400 white linen record cards, ruled in colours. It has twenty alphabetical, twenty monthly, and thirty-one daily guides. Here one can index customers and prospectives, with their addresses and general information. It is true that four hundred cards won't fill the larger galleries very long, but additional cards will cost us one dollar per thousand, and when the first box is filled one can buy another for sixty cents. Let this set of cards contain all the necessary data in connection with the filing of negatives, the delivery of proofs, as well as the names of every person who has come to your studio in the past years, and, no matter whether they ordered or not, follow them up. Don't let them forget for a day that you are ready, willing, and anxious to make the best pictures they ever

### Lists of Possible Customers.

A separate box should be used to record the arrival of the new babies that the stork brings to town, and another for the veterans and pioneers, for all the dear old folks past seventy need your special attention. They are treated to the down-hill of life. The sun will soon set for them,

must convince them and their loved ones that it is their duty to let us make a permanent portrait of the dear one who hasn't long to stay. Do it now. Go home and get after these folks. If you can't call on them, send somebody. If there's no one to send, write, not once, for one letter of this kind seldom brings results, but follow it up; try at least three times, if necessary, but don't give up until you are convinced that that particular person has no intention of contributing to your "bread and butter."

Buy still another box; this one only containing one hundred dollars or so, and use it as a record of the cost of the materials are consumed. Who sells you your supplies? How do you know that you can't save money by buying them from another fellow? Have you any record of the quotations that your firm in Portland made you last year? Aren't there a great many chemicals that you always buy in ounces, yet use in great quantities to justify purchasing in pounds? Amidol, metol, for instance, list at seventy-five cents an ounce, ten dollars per pound. Granting that you receive the same discount on both size bottles, the saving when buying in pounds is two dollars net. Figure pyro the same way, and you will find a clear saving of a dollar and a half. I take an interest in this as an example. Ounces are quoted at twenty-five cents and pounds at two dollars and fifty cents. Here's the "bread and butter" for you. Never use cheap chemicals. They are, always the most expensive.

### The Need of Advertising.

Keep books! Simple, plain, single-entry book-keeping is plenty good enough for most of us. Any book-keeper or business college graduate will be glad to start you in the right direction for a nominal sum. But know just "where you are at" at the end of each month, and have each day's work recorded in its proper place. Take advantage of your cash discounts, or, better still, pay cash, providing your ready funds will permit. Watch the little things, and advertise all the time. How? There are thousands of ways, and they are all good. A famous San Francisco photographer, now dead, used to advertise his business through his fine dogs. People were attracted by the dogs, and remembered and talked about the photographer. A Cleveland man advertises that he is the highest priced photographer in Ohio. A New York photographer said to a newspaper reporter who was an old friend: "Jim, say something about me in that paper of yours. If you don't know anything good, say something bad; but say something." The services of a printing press are as necessary to the success of a modern studio as that of a printing frame.

Make the public think about you all the time; then they can't possibly overlook you when they want pictures. Keep your prices up, keep your stock bills down, and root all the time. Go home and do just one of the many things I have suggested, and the bread-and-butter side of photography will immediately begin to look up.

## A PERMANENT SULPHITE SOLUTION.

E. KÖNIG, of Hoechst, in the current number of "Photochemische Korrespondenz," gives some details of a permanent solution of sodium sulphite, his satisfaction with which as regards keeping properties has been confirmed by a lengthy series of experiments. The solution is obtained from the commercial sodium bi-sulphite lye, which is neutralised with a solution of caustic potash, the result being a highly concentrated solution of sodium potassium sulphite, 3 ccs. of which correspond to 2 gms. of crystallised sodium sulphite. According to Dr. König's experiments this solution even when in only half-filled corked bottles preserves its properties undiminished for longer than a year. Carbonate of potash should be used for neutralising the bi-sulphite solution, inasmuch as a good deal of bi-carbonate is thereby formed, the restriction of which is very noticeable, particularly when alkaline developers are employed. As Namias has pointed out, a mixture of sodium bi-sulphite and carbonate of sodium developer is to be deprecated, on account of the formation of bicarbonate.

In order to prepare the permanent concentrated solution of white the following proportions should be followed: One litre of commercial fresh bi-sulphite lye of specific gravity 1.34, and containing practically 350 gms. of Na HSO<sub>3</sub>, mixed with a solution of 185 gms.; 100 per cent. caustic potash in about 400 ccs. of water. The last additions of caustic potash are carefully made, and the solution tested

by means of phenolphthalein, to see that it is alkaline. Indicators such as litmus and curcuma are useless for the purpose. The addition of the alkali should be made until the white phenolphthalein paper is turned red, and the solution is diluted to 1,270 ccs. It is then of a strength corresponding to 2 gms. of crystallised sulphite, or 1 gm. anhydrous sodium sulphite in 3 ccs. of the liquor. The neutralisation can be done, also, with a concentrated soda liquor, but in this case the anhydrous sodium sulphite separates out. It is not possible to make nearly such a concentrated solution by using the soda. The above method of preparing the sulphite solution will be seen to work out very cheaply from the following figures:—

One kilogramme bi-sulphite .....	.13 mks.
500 gms. caustic potash liquor, 36-38 per cent. ....	.18 mks.
1,270 ccs. sulphite liquor .....	.31 mks.

corresponding to 850 gms. crystallised sodium sulphite—that is to say that one kilogramme of the crystallised mixed potassium and sodium sulphite costs only .36 of one mark (= 4.32d.). It should be noted, of course, that in the preparation of the sulphite solution the pure chemical caustic potash is not employed, but the ordinary commercial caustic liquor.

\* Dr. König is evidently writing of the products above mentioned purchased on a manufacturing scale. The prices given do not apply to the retail market. In fact, the caustic liquor used for neutralisation is not an article obtainable retail in small quantities.

THE GRAND PRIX of the Milan Exhibition has been awarded to Messrs. Voigtländer and Sons for their photographic lenses.

PORTRAIT OF MARY QUEEN OF SCOTS.—If "Man of Kent," page 208, cannot obtain the above portrait, I have a 15 x 12 copperplate engraving in which the above Queen is shown in an oval, with appropriate design around, and should be pleased to make him a copy, or supply prints.—Archer Clarke, 20, Larkhall Rise, S.W.

ANATICS AND THE PHOTOGRAPHER.—Intelligence has just reached of a murderous attack on a French visitor at Fez. He was attempting to take a photograph of the sanctuary when he was set

upon by a number of fanatics and received severe injuries. He lies in a dangerous condition. Several arrests have been made, and the French authorities are demanding the immediate punishment of the offenders.

DR. GRÜN AS A SPY!—According to the "Daily Mirror," Dr. Edward Grün, the well-known exponent of large-aperture photography, while seeking moonlight photographs, was mistaken for a spy aiding plans for a German invasion. When the police, however, interviewed Dr. Grün, they found that he had been assisting the War Office in connection with tactical exercises in the district.

## EXPERIMENTS ON THE DEVELOPMENT OF THE LATENT IMAGE WITH INDOXYL COMPOUNDS.

(From Photographische "Korrespondenz.")

THE experiments described in my previous paper have proved that the image developed with indoxyl or thioindoxyl is not of a homogeneous nature, but consists of metallic silver and indigo or thioindigo. This corresponds with Lüppe-Cramer's statement of the nature of the negative image produced with ordinary developers.

We now come to the important question: Is the substance of the latent image of a homogeneous nature, and is the splitting into two only effected by development or fixation, or is the substance itself of the latent image not homogeneous?

The experiments already described show that the substance of the latent image, or a part of it, is an extraordinary oxidising agent, which can oxidise indoxyl to indigo and thioindoxyl to thioindigo.

If we adhere to the well-known sub-haloid theory of the latent image, we must come to the conclusion that silver sub-bromide must exert this action. It appears to me to be extremely improbable that such oxidising properties should exist in the sub-bromide, which is poorer in bromine, whilst the normal bromide, which is richer in bromine, behaves in an indifferent manner towards the two indoxyls. It would be much more probable to expect such an oxidising action with a per-bromide of silver. The results of the following experiment support this view.

An unexposed dry plate was bathed in the dark room in a 1:2,000 bromine water for fifteen minutes, then washed for an hour in running water and placed in a two per cent. aqueous solution of indoxyl. A development immediately resulted—that is to say, the plate became dark-coloured quickly. It was then washed for a short time and fixed in an acid fixing bath. When examined by daylight the fixed plate appeared a deep blue without metallic lustre; the blue "indigo image" dissolved immediately in a three per cent. faintly alkaline solution of sodium hydro-sulphite and a plate as clear as glass without a trace of a silver image was obtained. In order to exclude any possible action of the gelatine vehicle, an experiment was made with a bromide plate which was fixed, and therefore free from silver bromide. This was washed for two hours in running water, then bathed for fifteen minutes in bromine water 1:2,000, again washed for an hour in running water, and then immersed in a two per cent. solution of indoxyl. The plate remained colourless and clear as glass. The free bromine had obviously produced in the first case from the silver bromide the same substance which oxidised the indoxyl to indigo (in the latent image). As, however, the action of bromine on silver bromide cannot well form anything but a product richer in bromine—that is to say, a per-bromide—we must assume that the part of the latent image which oxidises indoxyl and thioindoxyl is a silver per-bromide. In contact, the per-bromide image, the indoxyl, is oxidised to indigo, and the chief image is itself reduced to silver bromide, not to metallic silver. The question now arises as to the formation in indoxyl development of the second or silver image. To this question the following experiment gives a satisfactory answer.

Professor R. Namias, of Milan, has found that a gelatino-bromide plate, on being bathed for a short time in a 1-200,000 solution of stannous chloride is brought into a "latent," that is, a developable condition, exactly as though it had been exposed. I have found Namias' statement to be correct, but at the same time I have determined that the "latent image" produced by stannous chloride differs in a very important detail from the true latent image obtained by exposure. It lacks the substance (silver perbromide) that oxidises indoxyl to indigo, which is contained in the substance of the latent image produced by light.

If an exposed dry plate is bathed for about ten minutes in a 1-200,000 stannous chloride solution, then washed for an hour in running water, and then placed in about a 2 per cent. solution of indoxyl, the plate is rapidly developed. If rinsed for a short time, fixed in an acid fixing bath, and examined by daylight, the fixed plate shows a black-brown silver image, and a trace of an indigo image. Naturally the plate becomes white in a sublimate bath, and bleaches glass-clear in a cyan bath.

The extremely dilute stannous chloride solution has thereby converted the silver bromide into the same substance as is the latent image caused by light, which substance, in contact with indoxyl, gives the silver image. As, however, stannous chloride is one of the most powerful reducers, the substance question must, in comparison with silver bromide, be a product poorer in bromine. Whether this is metallic silver ("silver germ") or a silver sub-bromide cannot be determined from the above experiments. Practically this is of no importance. One can assume a sub-bromide, for instance,  $\text{Ag}_2\text{Br}$ , decomposed into  $\text{Ag} + \text{AgBr}$ , in which sense it would act in the development that is to say, under the reducing action of the developer the silver atom, "the silver germ" would separate the silver bromide into silver and bromine, the former furnishing the silver image, the latter oxidising or forming a substitution product with the substance of the developer.

According to these views, one should have an indigo as well as a silver image when developing the "latent image" produced with stannous chloride with indoxyl, since the silver sub-bromide, or the complex  $\text{Ag} + \text{AgBr}$ , must act as an oxidising agent towards the indoxyl, even if it is infinitely milder than silver per-bromide.

In opposition to this it should be noted that indigo does not appear as the sole and only oxidation product of indoxyl; it is well known that indoxyl can be oxidised to indigo white and not to indigo by very weak oxidisers. Besides this, as mentioned above, in the splitting up the complex  $\text{Ag} + \text{AgBr}$  the bromine set free may act, not as an oxidiser, but as a substituting agent with the indoxyl.

According to these observations I am inclined to describe the substance of the latent light image as an equimolecular mixture of silver per-bromide and silver sub-bromide, the formation of which may be shown perhaps by the following equation:—

in which, in place of the sub-bromide,  $\text{Ag} + \text{AgBr}$  finally occurs. The existence of a per-bromide can certainly be assumed. Schmidt has proved the existence of a per-iodide (Zeit. f. Anorg. Chemie. IX., p. 418, Eder's Jahrbuch, 105, p. 88).

The development of the latent image caused by light, as an ordinary developer takes place, we may suppose, in the following manner:—The developer is oxidised by the silver sub-bromide, by which it is first converted into silver. If the developer gives a coloured oxidation product, then this is a part of the visible negative image. This assumption undoubtedly explains the totally different character of images obtained with different developers. The silver sub-bromide, the complex  $\text{Ag} + \text{AgBr}$  is then reduced to metallic silver by the developer, so that a silver germ action must be assumed very probable.

"Developers," therefore, are those substances which are capable of reducing the silver sub-bromide or the complex  $\text{Ag} + \text{AgBr}$  to metallic silver and bromine. B. HOMOLKA

## PRACTICAL HINTS ON PHOTOGRAPHING HEAVY MACHINERY AND ENGINEERING WORK.

[In the following article is continued the series of hints on the photography which is required by large engineering firms. The selection of apparatus and one or two useful preliminaries were dealt with last week.—Eds. "B.J."]

The preparation of large pieces of machinery for photographing is a very important part of our subject. In all Government work, which, of course, has to undergo a close inspection at the hands of officials, no painting or special preparation is permitted. The natural skin of the metal, either in its rough or finished tooled condition, must be maintained. On the other hand, where ordinary commercial jobs are concerned, many engineers make a rule to bestow good deal of preparation on their work by painting and hand planing, in order that it may be rendered specially suitable for a photograph. Others, again, among whom it may be stated are some of the highest class firms, rigidly set their faces against any special painting being resorted to for photographic purposes, confining their preparation merely to a careful hand cleaning and oiling by means of waste, etc., in any case quite a variety of colours are met with, ranging from black and dark olive green, down to red. Very often these surfaces partake of an enamelled form when cleaned up, and frequently give some trouble when a strong top light has to be used.

### Preparing the Subject.

In cases where painting is permitted, a good dark grey should be employed on such subjects as crank shafts and bright metal parts. The paint should yield a good matt surface when viewed from the standpoint of the camera, and if the job appears patchy, by likely by waiting an hour or so until the paint be quite dry, these patches will disappear. The unhardened paint is easily removed by exposure.

If, as is very often the case, the entire surroundings have to be blocked out on the negative, a colour should be chosen that will contrast with the margins of the machine showing a good contrast against a white background of the final print. This applies particularly to all attachments on the outline of the machine, which will not show well unless painted a dark colour.

Another very important matter when painting is performed is to be sure it is done just prior to the photograph being taken, so as to leave no opportunity for markings by the dirty hands of workmen. The lapse of a day or two often means that the job has to be repainted. In the case of inside portions of a machine being painted for the photographer the colour cannot be too white, and frequently great advantage can be gained by painting portions only of a subject, so as to bring up one part from the other. White paint is used for this, but much can be done also by chalk.

### The Advantages of Chalking Machinery.

In cases where large tools that are in daily use are concerned, painting, of course, is out of the question, but the same may be used up in an effective manner by means of a little chalk. First of all, the maker's name, which almost invariably will be found cast, or as a name-plate bolted on, or otherwise cast on some part of the tool, will call for attention. By chalking over the raised letters and then by means of the ball of the forefinger softening the chalk marks down, the same will be found to stand out in bold relief, and appear very telling in the finished photograph. Other things amenable to this treatment are the gearing wheels, springs, bolts, and any fine detail found in the dark portion of the object. It is really wonderful how the teeth of a gearing wheel may be made to show up in the finished photograph by means of careful preparation with a little chalk. A typical case may be mentioned. Since the introduction of electricity as a motive force to large lathes, etc., the gearing wheels form a very prominent part of the machine, in some of the newest patterns are enclosed in casings or covers, sometimes it is desired to photograph portions inside such casings without removing the entire cover, or, at least, to do so means of the cover door being open. By chalking the parts that appear through the open door they at once come into view, and show up well in detail in the finished photograph, otherwise they

would not appear at all, being simply buried in darkness. In cases also where outlines of portions of a tool are backed up with other dark parts, and therefore do not appear with enough contrast, much may be done by chalking the edges, so that they appear with a light line against a dark background. The lighting of the machines has often to be taken as it is found by the photographer, yet it is often possible to counterbalance the excess of top light (a usual defect) by making the ground into a reflector, as the writer remembers doing on one occasion, by having a concrete floor whitewashed, and so obtaining the detail in a machine, the projecting top rail of which cast a shadow over it. Similarly whitewashing all round a stationary engine will do a lot in the way of helping matters. In some instances very dark portions in large machines can be lighted by means of small electric lamps being placed so that the light is thrown on the parts it is desired to illuminate, the lamp, of course, being out of view. As a rule, such aids are but of low value, and require lengthy exposures, the light being very deceptive in its actinic value. The writer has also seen magnesium powder, with which a few grains of gunpowder was incorporated, prove of great service in lighting up hidden or dark recesses in heavy machinery; this, of course, requires to be burned in an open pan, simply igniting same with a smoker's vesuvian, stuck in the cleft of a long stick.

It often happens that makers desire a photograph of their tools as soon as possible after they are fitted up in some new shop, and before the flooring or other parts of the surroundings are in their finished condition. When this happens it is best to block out the entire floor space in the negative and print the same with a white floor, then sun down the whole portions and tone and fix as usual, and when the print is dry, by means of a parallel ruler, draw on the face of the print flag stones by means of cross lines at their proper angles. This looks well, and after the print is carefully doctored, the same is rephotographed. By this means nasty eyesores are got rid of. As to the method of working up the face of the print, the writer hopes to refer later on.

### Preparing Rough Castings for Photography.

The preparation of large steel castings for the purpose of being photographed differs materially from that of ordinary finished machinery. Such pieces are often met with of great weight, in some cases running as high as forty tons, and varying in shape and dimensions after these pass through the dressing shop. They are generally photographed without any painting. In this condition the pieces are likely to appear somewhat patchy, and show an abundance of chisel marks from the hands of the dressers. In the rough casting these marks will very likely, at certain angles of lighting, present a bright silvery appearance, quite unlike the dull grey look of the rest of the piece, whilst in other portions large patches of darker coloured metal will almost be sure to be present.

The writer knows of no better method of getting rid of these markings and eyesores than by forcibly throwing or dusting the moulder's sand on such parts as require to be doctored. In all dressing shops these castings will be found simply smothered in such sand, so there is no lack of supply. After the dry sand is forcibly thrown upon the parts the surface is gently dusted over with a little dry waste, and immediately a practised eye will be satisfied with the improvement effected. Bright glaring chisel marks will be seen to disappear, and large patches of dark metallic appearance will show up as grey as the rest of the piece. In all rough castings, even at the stage where such leave the dressers' hands, there will be on the surface small holes or indents which appear in exaggerated form under side lighting. It is always advisable to doctor the more pronounced of them before exposing the plate. For this nothing is better than a little moulder's putty, which, when applied to fill up these little holes, may at first show up as dark dots against the light grey colour of the casting; but another few

handfuls of dry moulder's sand thrown forcibly on them soon make them vanish.

In nearly all marine and engineering castings there will be found large and small apertures with sharp edges. All moulders like these lines or sharp edges to be well shown in the photograph, a great aid being to "dress" the castings beforehand with chalk, as before stated, and then the lines can be either intensified on the negative or on the print. With too much front or too low a light these apertures will often show a lack of shadow, and tend to spoil the solidity of the piece. The natural remedy is to select a better lighting, but where this cannot be done an immense amount can be put in on the print. The photographer of machines soon finds that he must use brush and air-brush in the perfection of his work.

#### Preventives of Halation.

Halation will often be found difficult to prevent, especially when working right up against a strong light. If the subject be situated and a fixture under the worst possible conditions, it is often best to blind off the window with brown paper. This can be had in web of almost any size and shape, so as to cover all the glass, and in such cases the negative will require to be carefully treated and

blocked out. Other cases where bad lights are situated at large distances in front can generally be treated in some way or other by boarding up or hanging shields from a crane, etc., so that the evil is prevented. Prevention is always better than cure, and may be done by choosing the hour for exposure when the direct light is not present. As to backing the plate, the writer's experience is that bitumen dissolved in chloroform is the best to employ when this is used the plate is developed without previously removing the backing. A little practice will soon make a regular worker quick at home in developing after this method.

The working up of the print preparatory to rephotographing it is perhaps the most difficult of all operations connected with this class of work. It takes some experience to be an adept at it, but the air-brush has placed a new power in the photographer's hands, and all high-class block makers know the value to place upon such method of working up a photograph. No doubt quite a lot can be done by the brush alone, but for really high-class finish highly glazed prints, which are so much in request for fine detail in process work, only the best results can be obtained by an expert in the use of the air-brush.

T. NEWTON ARMSTRONG

## FLASHLIGHT PORTRAITS.

[A branch of work in regard to which our advice is often asked by "St. Louis and Canadian Photographer," by Mr. Felix Raymer, who gives the examples, reproduced in our contemporary, should be—Eds. "B.J."]

ONE of the most pleasant and profitable branches of work for the photographer is that of taking portraits at home of friends and patrons by the use of flashlight. This branch of photography appeals to nearly everyone that has ever tried it, from the mere novice to the old experienced operator. We have been using the flashlight method for making portraits for many years, but there is always a charm in every negative we make with it that never wears upon our nerves.

The amateur may gratify this desire for making flashlight pictures at but a trifling cost, as there are many small hand machines on the market that sell for a very little, or he may use the flash sheets, which can be obtained at a small cost.

To make pictures with the flash it is necessary that one have some knowledge of the making of pictures by daylight, but it is not necessary that one be a crack operator if clear and concise directions are followed for placing the camera and the flash machine. I will try and give such directions, and will use a flashlight portrait to illustrate the method and effect of the light.

#### A System for Flash Portraits.

We must imagine the subject as the hub of a wheel, and in our mind's eye draw a circle around her, and this circle will be the rim of the wheel. Now the flash lamp or the flash sheets, whatever is used, should be placed at some point on this rim, and its station on the rim will control the effect of the lighting. If it is at some certain station, the effect of the light on the face will be entirely different from that which would be secured if it was placed at some other station. These stations will represent the "spokes" of the wheel. By reference to the small drawing our meaning can be easily seen.

To secure the effect known as plain lighting, in which there is a three-quarter view of the face, with more of the face in light than in shadow (the kind of lighting which is most suitable for the great majority of sitters), the flash should be stationed at the spoke in the wheel that is numbered "2A," and the camera at "1." And to get the right view of the face, the operator should take his stand at station "2," and then have the subject turn from him until he just misses seeing the ear on the far side of the head.

The imaginary circle about the subject should be about five or six feet in diameter, and the lamp or flash, whatever its nature, should be raised above the subject's head, but held over its proper station, to about four feet in height. A few trials will have to be made before the exact height will be fully understood. But after the first trial the negative should be examined carefully to ascertain if all of the points that go to make up this effect of lighting have been secured. If there is no light in the eyes it shows the lamp was

less experienced readers is the subject of some useful notes in this advocates a system which is easily comprehended, and which, according to sufficient for the purposes to which flashlight work is usually applied.

raised too high above the subject's head, and the brows shadowed the eyes so that the light could not get to them. On the other hand, the little spark of light falls on the side of the iris it shows that the flash was held too low. In either case the second trial should result in a better position of the darts of light. The correct position for them is on the edge of the iris, midway between the top and side. By imagining the small drawing which we use and which is referred to as a wheel, to be the iris of the eye, we will say that the darts of light should fall at the point where the spoke is marked "1," or if the light is placed on the opposite side of the face the spoke that is marked "1A" will be the right place for the dart of light.

#### A Characteristic of the Lighting.

Everything depends upon this little dart of light in the eyes. If they are absent it is a foregone conclusion that the lighting is wrong. There is nothing in the entire lighting that can be right if these little darts of light are lacking. Therefore I wish to impress

upon the readers the importance of working to get them. After a few trials it will be an easy thing to get them, for they are dependent upon only two conditions:—First, the height of the flash, which has been mentioned; second, upon the facing of the subject to or from the light. If the operator has chosen the wrong station when he placed the flash at spoke "2," as, for example, he may have gone far to one side, it will cause the light to fall more to the rear of

subject than it should to get the light in the eyes. Remember to take the station first, and have the subject turn from the operator until the ear on the far side of the face is just out of sight, and if the flash is placed at this point the light will fall in both eyes. If it falls in one eye, and that is the eye on the side next to the flash, but does not fall in the shadow eye, it shows that the flash was too far toward the rear of the subject, but not too high. If it does not show in either eye it shows that the flash was too high. With a little study this feature of the work can be understood, although it may seem rather difficult at first reading.

To secure the best results the flash and the pressure of the bulb releasing the shutter should be simultaneous. To have it so, all that is necessary is to have a "Y" made of hollow brass tubing, about the size of the rubber tubing used on the bulb. This "Y" can be made at any tinkers', and each prong of it should be about two inches long. When ready to make the exposure the rubber tubing leading from the shutter should be slipped over one prong of the "Y" and the tubing leading to the lamp (this is assuming that a flash lamp is to be used, and not sheets) should be slipped over another prong of the "Y" and a tube should lead from the bulb to the remaining prong of the "Y." This makes it possible to press the bulb, and both the lamp and the shutter flashed and exposed at the same time. The shutter should be standing on "bulb pressure" if it be one of the automatic pattern. About one teaspoonful of any flash powder will be right for a 5 x 7 plate.

If the flash sheets are to be used they should be pinned on a board in such a way that one will ignite the other, so that all may be burned in the exposure. The more exposure necessary the more of the sheets will have to be used. Pin them over the board so that the corners will lap over each other, and when the exposure is to be made open the shutter and ignite the lowest sheet at the corner. All other light should be closed out of the room, if the sheets are used, as they burn longer than flash powder, and a move may result, especially if the subject be a little nervous. The board containing the sheets should be stationed at the spoke marked "2," as described above, and should be raised above the head as mentioned in connection with the lamp. In fact, all directions for working the sheets are the same as though a flash lamp was used.

If the flash is to be made with one of the hand lamps or pistols that are advertised, everything should be the same, except the operator will have to hold the flash in his hand, but it should be done from the same station or spoke, and at the same height as explained in connection with the lamp. All flashes should come from the same direction, it matters not what medium is used to get them. The developing of plates is the same, except that a flash starts as though it were under-exposed. But leave it alone and it will come out all right. Few flash lights are ever over-exposed. If such a thing should occur, treat the negative the same as though it was made by daylight.

#### THE PHOTOGRAPHIC CONVENTION AT HEREFORD IN JULY.

The following is the preliminary announcement of the programme of the Convention at its forthcoming meeting in July next under the presidency of Mr. Alfred Watkins, J.P. The General Secretary of the Convention, Mr. F. A. Bridge, East Lodge, Dalston Lane, London, N.E., will send a copy of the programme to any photographer anxious to take part in the Convention.

MONDAY, JULY 15.

*Morning.*—Conducted parties to places of interest in and around the City.

*Afternoon at 2.30.*—The members will be welcomed to the City by His Worship the Mayor, Mr. G. J. Caldwell, J.P., who will be supported by members of the Town Council, the President, J. S. Arkwright, Esq., M.P., and Committee of the Herefordshire Photographic Society, and members of the Woolhope Club.

*At 3 o'clock.*—The President, Mr. Alfred Watkins, J.P., will deliver his inaugural address, after which the following paper will be read:—"Microscopical Researches on the Gelatine Film," by Dr. V. Scheffer.

*Evening at 8.*—Conversazione. Official reception by the Mayor of Hereford. Exhibition of pictures and apparatus, musical promenade, refreshments, etc.; also an exhibition of Hereford City Insignia,

plate and ancient charters, which will be specially arranged by Mr. W. T. Carless, the Hon. local Secretary.

TUESDAY, JULY 16.

*Morning.*—Excursion by brakes to Weobly and Pembridge.

*Evening at 8.30.*—Annual General Meeting, to be followed by a meeting of the New Council.

WEDNESDAY, JULY 17.

*Morning.*—Visit to the cathedral, the markets, churches, hospitals, etc.

*Afternoon.*—The President and Mrs. Watkins' "At Home," at the Vineyard Croft. Boating, punting on the Wye, cattle studies, woodland bits. The official Convention Group, etc.

*Evening at 7.*—Annual dinner at the "Green Dragon Hotel."

THURSDAY, JULY 18

*Morning.*—Excursion to Ludlow, Stokesay, etc.

*Evening at 8.30.*—A paper by Mr. E. J. Humphery—"A New Aid to Pictorial Photography."

FRIDAY, JULY 19.

*Morning.* Excursion to Goodrich, etc.

*Evening at 8.30.*—A lecture, entitled "The Romance of Insect Life," by Mr. F. Martin Duncan.

SATURDAY, JULY 20.

*Morning.*—Half-day excursion to Ledbury.

*Place of Meeting.*—By the courtesy of the Corporation of Hereford the use of the handsome Town Hall and a suite of rooms have been placed at the disposal of the Convention for the week.

*Exhibitions.*—The usual Trade Exhibition of apparatus, pictures, etc., will be held, and every effort will be made to render it attractive and up-to-date. Demonstrations of new processes will be arranged if possible.

The City of Hereford is rich in ancient charters and documents from the time of Richard I. It also possesses a fine collection of old and valuable plate, etc. The Exhibition therefore, which will be arranged by Mr. W. T. Carless, should be of exceptional interest.

There will also be an exhibition of photographs by members of the Herefordshire Photographic Society, the series including views of many of the places to be visited during the meeting.

*Hereford Cathedral.*—The Dean of Hereford (the Hon. and Very Rev. J. W. Leigh, D.D., F.S.A.), will arrange to meet the members at the Cathedral on Wednesday morning, July 17, and will see that the many attractions are pointed out. Members wearing their badges will be permitted to photograph in the cathedral at any time during Convention week, except when there is a service.

*Excursions.*—The excursions will be inexpensive, and ample time will be allowed for photography.

*Professional Photography.*—A desire having been expressed that professional photographers attending the Convention should have opportunities afforded them for informal chats on business matters, a special room at the Town Hall will be provided for this purpose on Thursday and Friday evenings, July 18 and 19, at seven o'clock.

*Accommodation, Etc.*—For further particulars, list of hotels, apartments, dark rooms, dealers, etc., etc., see the Official Illustrated Handbook, which will be issued to members as soon as possible.

#### SURREY PHOTOGRAPHIC SURVEY.

The Mayor of Croydon (Mr. H. Keatley Moore) presided on Saturday last at the annual meeting of the Photographic Survey and Record of Surrey, held at Croydon Town Hall. During the year three hundred and seventy-one photographs were added to the society's collection, bringing the total to two thousand three hundred and forty. The Mayor urged members to specialise in their photographic work, so as to enhance the value of the collection of prints for public reference. On the motion of Mr. Hector Maclean, the Croydon Public Libraries Committee was heartily thanked for the practical assistance and encouragement given to the society. Mr. Maclean thought it possible by extra effort to secure an average of one thousand prints yearly for the collection.

KIDDERMINSTER PHOTOGRAPHIC SOCIETY.—Mr. W. Weaver Baker, Westcliffe, Chester Road, has been appointed honorary secretary in succession to Mr. G. F. Griffin, who has taken over the treasurership.

## JONATHAN FALLOWFIELD—THE FIRM'S JUBILEE.

THE house of Fallowfield is to be congratulated on having completed an honourable record of more than fifty years of photographic material dealing. The original business was started in 1855 as a chemist's by Mr. Jonathan Fallowfield, who was, we believe, the first to sell the ferrotypes, which had been introduced from America the year before. The records of these early days are scanty, but it is interesting to note that in 1870 the commercial side was restricted solely to goods and cameras for ferrotypes and wet plates only, and even in 1880 sensitised paper was ordered by the firm in ten-ream lots. The business of Jonathan Fallowfield from its earliest days may be said to have been an outward and visible sign of photographic progress, and the catalogues issued by the firm will doubtless provide material for future historians anxious to obtain a bird's-eye view of photography as practised in any given period. The present writer recollects how his first materials for photography were selected from the red-covered list of the firm of Fallowfield, issued in 1887, a volume which, with succeeding editions, has at length attained a size and copulency, the equal, if not the superior, of any other annual publication.

In 1888 the entire business was bought by Mr. F. W. Hindley, and two years later the photographic portion was removed from the Marsh, Lambeth, to the present address; the chemist part was sold, and still remains on the original spot. The business is now under the management of Mr. Duncan Hindley, who with his father has evidently preserved the happiest relations with their staff, if the proceedings on Monday last may be taken as expressive of their feelings. To mark the successful completion of half a century's steady progress a dinner and smoking concert was held at Frascati's Restaurant.

Mr. F. W. Hindley presided at both events, and at the dinner his guests included Messrs. Kemp Welch (Iford, Ltd.), W. Fullicks, Frank Johnson, A. E. Staley, T. K. Grant (Lumière, N. A., Co.), Ernest Whitfield (Paget Plate Co.), Charles Winter (Imperial Plate Co.), S. Herbert Fry, A. Horsley Hinton, P. R. Salmon, F. J. Mortimer, H. Snowden Ward; and of the firm, Messrs. F. Duncan Hindley, F. J. Goode, W. C. Hardiman, Traise, Wallach, Bennett, Weeks, Ingle, Preece, Sadler, Goulding, Woodward, Fellowes, Fitch, Collis, Podger, Boxall, Carpenter, Marshall, Berry, Collins, Myer, and Trendell.

Notes and telegrams of congratulation were read from Messrs. Jonathan Fallowfield, A. Harman, R. Child Bayley, J. B. B. Wellington, A. Hall, S. H. Wratten, A. C. Brookes, George E. Brown, and Dr. Acworth.

After dinner the time was short, but half a dozen toasts were drunk with enthusiasm, the list, with proposers and responders, being: "The King, Queen, and Royal Family," the chairman; "The Firm," Mr. H. Snowden Ward, Mr. F. W. Hindley; "The Staff," Mr. F. Duncan Hindley, Mr. F. J. Goode; "The Trade," Mr. A. Horsley Hinton, Mr. C. Winter; "The Press," Mr. S. Herbert Fry, Mr. P. R. Salmon; and "The Chairman," proposed by Mr. A. E. Staley.

The chairman, in a most interesting reminiscent speech, said that he believed the business had been built entirely upon the old-fashioned principles of honest trading, promptitude, and consider-

ation of customers' wishes. He rejoiced in the earnest support of a loyal staff, not one member of which had come away from any other photo-material business.

Mr. Duncan Hindley, who fully shares his father's popularity, said that while there was one member of the staff (Mr. F. J. Goode), with a record of twenty-five years' service, and another (Mr. Fellowes) with twenty-two years, it was a young staff, for the average age was under thirty, although the average length of service of the members was over eleven years. There were seven members with more than fifteen years' service, and of the nine departments into which the business was divided, every head had been with the firm for over eleven years.

For the concert, a capital varied programme had been arranged by Mr. Willie Rouse, under a committee consisting of Messrs. H. W. Fitch, F. J. Goode, W. C. Hardiman, H. J. Traise, and F. E. Trendell, with Mr. F. Duncan Hindley as hon. sec., and Mr. J. C. Preece as hon. assistant sec. The whole proceedings were marked by the greatest heartiness, and the roof seemed like lifting when

The Fallowfield Jubilee, March 18, 1907. Photograph of the Dinner by Jacks & Co., Glasshouse Street, W.

the whole party, of some three hundred and fifty, gave "musical honours" to Mr. F. W. Hindley, on the proposal of Mr. Fellowes, seconded by Mr. Hardiman.

## PHOTOGRAPHIC SURVEY OF SUSSEX.

THE annual meeting of the Photographic Survey and Record of Sussex was held at the Brighton Public Library on March 12, the Mayor of Brighton (Councillor Gervis) presiding. The report of the Survey has already been given in our columns, and it is therefore unnecessary to say more than that it was adopted at the meeting, and that appreciation was expressed of the labours of the officers, and in particular of those of Mr. J. C. Stenning, the originator of the Survey, who has acted as its honorary treasurer. At the present time 750 photographs have been secured, 1,100 negatives, and 300 lantern slides, all of which are to be deposited in the Brighton Free Library. It is satisfactory to note that the services of Mr. H. D. Roberts, librarian to the Brighton Municipality, have been retained, he having consented to act as honorary curator and to catalogue and re-arrange the specimens as soon as they are placed in his charge. The Brighton Corporation has voted a small sum of money for the provision of cases in which the photographs and negatives are to be preserved.

In the course of the discussion which followed the Mayor's speech, suggestion was made by Councillor Griffith that in addition to the

photographic survey, phonographic records of the Sussex dialect should be obtained.

The officers for the forthcoming year were elected, and it was stated that the Duke of Norfolk, who is abroad, had been invited to become president.

#### THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

The annual general meeting of the Professional Photographers' Association was held at the Royal Photographic Society, 66, Russell Square, W.C., on Friday, March 8, Mr. Martin Jacolette in the chair.

The report of the Committee was read.

##### REPORT OF THE COMMITTEE.

The most notable feature of the past year has been the evidence of increasing interest in the Association, and recognition of its usefulness to the profession, afforded by the influx of new members. During the twelve months covered by the present report, 77 new members have been admitted. This compares with 53 for the period of seventeen months covered by last year's report. There have been 22 losses through death or from resignation, members having given up business or removed, leaving no address, and 50 members have failed to pay their subscriptions for two years after eight applications. The total membership is therefore 524.

In accordance with the notification made at last year's annual general meeting, a sub-committee, appointed by the Committee, fully considered the position of the assistants' certificates scheme, and, in accordance with their report, the Committee sanctioned the institution of a new kind of certificate to be known as the general assistants' certificate, and, in order that no one should be deterred from application on the ground of not being able to afford the expense, the inclusive fee was fixed at one shilling. The Committee now regret to report that their scheme met with so little support at the hands of assistants, that the expense of continuing the weekly advertisement was deemed unjustifiable, and it was withdrawn.

At the invitation of the Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY, the Committee organised a small exhibition of members' work, which was held at the Gallery attached to the office of the JOURNAL, from October 11 to November 10, last year. There were seventy-nine exhibiting members, each sending one work. The character of the work exhibited was rather severely criticised in some quarters, but on the whole, not unjustifiably. In some respects the conditions it was thought necessary to make in a first exhibition of the kind were not conducive to a strong exhibition, but on the whole the experiment was sufficiently successful to make it worth while to make another attempt during the present year should opportunity occur.

The number of applications from members for advice and assistance in business difficulties continues large, and in most cases the aid of the Association has enabled the difficulty to be met successfully.

The new Copyright Bill promoted by the Artistic Copyright Society is calculated to curtail the privileges of photographers with regard to their copyrights considerably. A sub-committee is now actively engaged in negotiations with that Society with a view to equitable treatment of photographers in the Bill to be presented to Parliament; but it is necessary to warn members that the apathy of photographers generally in a matter that so intimately concerns their interests, seriously impairs our representatives' authority. The opposing interest, that of the illustrated press, is an extremely powerful one, and to enable us to combat it successfully requires at least that photographers should show an intention of fighting for their rights.

During the year the Transvaal Professional Photographers' Association has been formed, and the Committee have established corresponding relations with it with a view to mutual assistance.

Arrangements are now being made with the Fine Art and General Insurance Company for insuring the risks of members under the Workmen's Compensation Act, 1906.

The Committee, mindful of the injury done to photographers arising on legitimate business, by the system of canvassing for free enlargements, etc., have made strenuous endeavours to find means to combat an evil. Their efforts have been of little effect on account of the impossibility of inducing photographers whose businesses are affected to assist them in any way. For instance, an

offer to provide handbills calling attention to the nature of the free portrait swindle, for distribution, which appeared in the January "Circular," was only responded to by one member.

The death of Mr. William Grove, Hon. Treasurer and Secretary, which took place early in the year under review, deprived the Committee of a friend whose counsels were always wise and the Association of an officer whose labours in its interest cannot be overestimated in value.

The thanks of the Association are due to the Royal Photographic Society for allowing the meeting to take place at their house, and to the Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY for publishing notices, reports, and other information relating to the Association. The Committee also wish to express their indebtedness to the Hon. Solicitor, Mr. Percy E. Marshall, for the valuable assistance he has rendered them.—By order of the Committee,

ALEXANDER MACKIE, Hon. Secretary.

In the course of the discussion thereon, the Hon. Secretary said that since the publication of the last "Circular," in which the terms for insurance under the Workmen's Compensation Act offered the members by the Fine Art and General Insurance Company were published, a communication had been received from the company in which they proposed to modify the method of charging. Under the new method the minimum would be 5s., subject to the usual allowance to members upon the aggregate wages and salaries paid.

Mr. Ellis pointed out that one of the advantages of the percentage (on the gross salaries) system was that it would cover casual or season engagements.

A discussion, in which several members took part, ensued upon various points and details regarding the Act.

In reference to a subject dealt with in the report—the free portrait swindle—the Hon. Secretary said:—Of course the members had noticed that the Association was continually dealing with the free portrait swindle. A great many complaints had been received from members in connection with this and requests for assistance. In answer to these requests he was accustomed to write:—"If you can get an actual case of fraud the Committee will take it up," but in no case had he received a reply to his letter. In the January number of the "Circular" an offer was made to print a circular notice calling the attention of the public to the swindle, and supply members with copies at practically the cost of the paper. One member only replied asking the cost of the circulars. He had, however, recently received a letter from Mr. Greenway, of Northampton, from which it would appear that the photographers of that town had combined and were taking action in the matter, and that they would probably succeed. The following advertisement had been inserted in the local papers:

#### FREE PHOTOGRAPHIC ENLARGEMENTS.

ANY NORTHAMPTON RESIDENT who has ANY GRIEVANCE against the OUTSIDE FIRMS who are "Working" this Town with their so-called "Free" Enlargements, are REQUESTED to COMMUNICATE with the undersigned Members of the Professional Photographers' Association of Great Britain—the Executive of which is combating this unfair competition.

(Here followed the names of six local photographers.)

It had been suggested to the Associated Northampton Photographers that they should vary the terms of their advertisement from time to time, and that they should also refer to the Secretary of the Professional Photographers' Association as willing to give advice, and, if necessary, supply legal assistance in cases of fraud. A good suggestion has been made at one of the Committee meetings that the Association should be prepared to supply a letter addressed to the editor of the local paper for publication in the correspondence columns calling attention to the nature of the swindle. This matter was in hand, and in a few days copies of the letter would be available for use in the way indicated.

With regard to the new Copyright Act, members were aware of the fact that in the Bill being promoted by the Artistic Copyright Society, as it stands at present, it was made a condition of copyright, as regards photography, that every photograph issued should be marked with the names of the proprietors of the copyright, the date it was taken, and the letter "C," and that there would be no infringement if the person reproducing the photograph could show that he relied on an unmarked copy, and that he had no knowledge that the photograph was copyright. The difficulties attached to obligatory marking would be obvious to all. In the first place, a

photograph was the only kind of work subject to artistic copyright which could not be marked by the same process used in its production. A painting could be marked in paint, an engraving, which must be printed with a margin, could have the mark engraved on the margin, and so on; but to mark a photograph entailed an after process, involving trouble and expense. Further causes of objection to the proposed system was that a photograph had no natural margin. The mark would naturally be placed as near the margin as possible to avoid disfiguring it. To trim the mark off would be easy, and no one into whose hands the trimmed print fell could tell whether or not it was issued in the state it then appeared. In that case practically the unfortunate proprietor would have no remedy. Amicable negotiations are being conducted with the Artistic Copyright Society, and it was hoped a compromise would be arrived at satisfactory to all interested.

The report was then adopted.

The Hon. Treasurer, Mr. Lang Sims, brought forward a statement of accounts which showed that the Association was in a sound condition financially.

The following were then elected officers of the Association for the ensuing year:—

President: Henry Chas. Spink (Brighton).

Members of Committee:

London.	Country.
Bridge, F. A.	Abraham, G. P. (Kewick).
Ellis, Alfred.	Bacon, W. H. (Newcastle).
Elliot, Ernest C.	Birtles, T. (Warrington).
Fry, Herbert S.	Chapman, J.P., H. A. (Swansea).
Hull, H. Edmonds.	Comley, Hy. J. (Stroud).
Mackie, Alexander.	Gill, Wm. (Colchester).
Mendelssohn, H. S.	Lankester, P. (Tunbridge Wells).
Prodger, Daniel.	Moffat, F. P. (Edinburgh).
Scamell, Edgar.	Mowll, A. F. (Liverpool).
Sims, Lang.	Robinson, R. W. (Redhill).
Skillman, C. H.	Rowe, T. (Eastbourne).
Willson, R. Fellows.	Turner, T. C. (Hull).

In vacating his seat, the retiring President congratulated Mr. Spink on his election, and wished him a happy and prosperous year of office. Mr. Spink then took the chair, and was invested with the President's Badge.

The President returned thanks for the honour the members had conferred on him, and said the pleasing duty devolved on him of asking Mr. Jacolette to accept a replica in gold of the central portion of the President's Badge as a souvenir of his year of office, the gift of the members of the Committee. Mr. Jacolette thanked his fellow members in suitable terms.

Messrs. Frank Turner and C. St. J. Vaughan were elected auditors of accounts.

An alteration of Rule 12, by the omission of the final words "at nine o'clock," was proposed by Mr. Lang Sims and carried.

Votes of thanks to the retiring President, to the other officers, and Committee, and to the auditors, and the responses thereto, closed the proceedings.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between March 4 to March 9:—

**FLASHLIGHT APPARATUS.**—No. 5,171. Improvements in gas flashlight apparatus. Ernest Wagnmuller, 3, Stubenrauchplatz, Steglitz, Berlin.

**TELEPHOTOGRAPHY.**—No. 5,187. Process and apparatus for the electrical transmission of half-tone photographs, drawings, etc., Henri Carbonelle, 111, Hatton Garden, London.

**CAMERAS.**—No. 5,308. Improvements in portable or hand photographic cameras. William Watson, 45, Chestnut Walk, Walthamstow, London.

**TRIPOD HEAD.**—No. 5,371. Improved turntable head for camera tripod. Charles Henry Mills, 95, Day's Road, Bristol.

**LENSES.**—No. 5,406. Improvements in photographic and projection lenses. Conrad Beck, 68, Cornhill, London.

**CAMERAS.**—No. 5,411. Improvements in photographic cameras. Arthur Lewis Adams, 26, Charing Cross Road, London.

**GLAZING PRINTS.**—No. 5,413. Improved process and means for pressing or glazing prints, pictures, photographic, and other papers and the like. Benno Borzykowski, 37, Chancery Lane, London.

**TRIMMING PRINTS.**—No. 5,500. Improvements in apparatus for cutting or trimming photographic or other prints. John Ashton Mann, 11, Southampton Buildings, London.

**CINEMATOGRAH LENSES.**—No. 5,504. Improvements in cinematograph lenses for wide angle work. Robert Alfred Ives, The Northampton Institute, London.

**TELEPHOTOGRAPHY.**—No. 5,514. Improvements in the reproduction of drawings and the transmission of pictures by telegraph. Sherard Osborn Cowper Coles, 82, Victoria Street, Westminster, London.

**TELEPHOTOGRAPHY.**—No. 5,635. Improvements in the transmission of pictures and messages. Sherard Osborn Cowper Coles, 82, Victoria Street, Westminster, London.

**COLOUR PHOTOGRAPHY.**—No. 5,692. Improvements in the production in colour of pictures of an object photographed by means of a combination of photography with a particular four colours in pigments or dyes. George Woodiwiss, Sunbridge Chambers, Bradford, Yorks.

**TELEPHOTO LENSES.**—No. 5,719. Improvements in telephoto lenses. Owen Wheeler, 68, Cornhill, London.

**PICTURES.**—No. 5,726. Improvements in the production of pictures. Sherard Osborn Cowper Coles, 82, Victoria Street, Westminster.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

The following complete specification is open to public inspection before acceptance under the Patents Act, 1901:—

**COLOUR PHOTOGRAPHY.**—No. 4,932, 1907. Method of producing photographs in natural colours. Brasseur.

## New Trade Names.

**WELLINGTON.**—The design of a label, including the words "Wellington Slow Contact Paper, S.C.P." To be kept dry. Open in weak artificial light. Manufactured by Wellington and Ward, Elstree, Herts. Photographic Paper. Wellington and Ward, The Elms, Shenly Road, Elstree, Herts. November 28, 1906.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Flower Portraiture.

Mr. Lionel Haweis, in recommending flower portraiture as an effective method of learning the principles of lighting, writes, in the elegant Spring Number of the "Amateur Photographer":

"The room I hired had but one window, set almost in the corner of it. . . . Parallel with the window, and lengthwise, I placed an ordinary deal table, the narrow end up against the partition wall, so that the centre of the table measured about four feet from my only source of light. Then I tacked a white uncreased sheet of paper to the partition wall two feet above table level, to hang against the wall down on to and along the table in the direction of my quarter-plate camera, perched, if you will, on some books. By this simple means I accomplished a capital continuation background."

"My attention was next directed to the window, which I curtained first with white muslin from top to bottom, and over that with dark blue sateen in two sections—one curtain for top light, and one for side light—to slide with small rings along wires. The light I then found was entirely under control."

### Photographing Boating Crews.

The best position, in my opinion, to take an eight in action (writes M. Alphonse Abrahams, in the "Photographic News," for March 15) is from a bridge, pointing the camera down to the water. The chief difficulty encountered is the distance that boat must necessarily be from the camera, so that it is absolutely essential to use a long focus lens. If a bridge does not occur in any part of the course the boat will traverse, the snap must be made from a bank, and it is well to avoid a high bank, since a picture from a small height

above the water, say, 10 or 12 feet, does not look well, and tends to exaggerate any unæsthetic peculiarities of the oarsmen. In this connection I would say snap at the beginning of the stroke rather than at the finish. Snapping a boat on the level involves only one difficulty, and that is uncertainty of focus. You can never be sure exactly which part of the river the eight will traverse, and the best plan is to carefully watch the course on one day and proceed next day to photograph at the same spot. A good cox steers an ideal course almost daily, so that you may be pretty sure he will not be far out two consecutive days. Another good plan is to follow the crew on a bicycle till they "easy," then run in front for forty or fifty yards. From the direction of the boat's bows you can determine the course it will take past you.

#### Altering Backgrounds in Portrait Negatives.

The best plan (writes "Præcious," in "Photography," for March 9) is to make a print on glossy bromide, getting the figure the right strength, and ignoring altogether the darkness or lightness of the background. It is to be covered up, so it does not matter. Instead of making a contact print, an enlargement three or four times (linear) the size of the original negative makes the work easier and the final result better. Next, some "body colour" must be mixed up. This is made by adding to a thick cream of Chinese white a little neutral tint water colour, the white being necessary to form a body colour—that is to say, an opaque colour which will not allow anything underneath it, whether lighter or darker, to show through. With a fine brush the figure is carefully outlined with this body colour, taking great care not to trespass on the figure itself to the slightest degree, and then with a bigger brush the rest of the background may be covered up. Plenty of colour should be put on, and allowed to get thoroughly dry. The enlargement or print is then fixed up in a good light and photographed down to its original size again, and from the negative so made any number of prints can be got in the usual way. This process gives much better results than can be obtained from mere blocking out of the negative.

#### Controllable Control.

Shielding by means of thin pieces of wood or card (writes Mr. F. W. Bennett, in "Focus") forms the most simple means of modifying negatives during printing. And the difference that can be produced by simple shielding is very great. The card can be supported above the printing frame, the height and arrangement depending on the effect desired. This method is simply vignetting, as adopted for many portraits. For this and the other methods of control illustrated, it is imperative that the printing should be done in a diffused light, and that the frame should be in a horizontal position.

The part of the negative uncovered by the card prints fully; underneath the card the action of the light gradually decreases until it almost ceases. The distance at which there is only a slight action depends on the height of the card shield above the surface of the negative. By regulating this height, any desired degree of softening may be obtained.

A small corner of the larger part of a negative may be shielded in this manner, according to the effect desired. Two shields may be shaped so as to follow the form of a prominent line in a landscape. As another example, a hole may be cut in a piece of card and the card supported over the frame so that the hole is just over a light spot in the picture.

#### CATALOGUES AND TRADE NOTICES.

OUR Liverpool readers should make a note of the new list from that popular purveyor of photographic supplies, Mr. Fred V. A. Lloyd, of 15, Lord Street. The list makes a judicious selection of the most approved apparatus, and gives particulars of the developers and printing enlarging obtainable from Mr. Lloyd.

ESSERY, HOSKING, AND CO., LTD.—Registered March 8. Capital 400, in £1 shares. Objects: To acquire the business carried on at 4-5, Morley Street, Plymouth, by W. Essery, and to carry on the business of chemists, druggists, patent medicine vendors, manufacturers of medical, surgical, and photographic appliances, etc. No initial public issue. Registered without articles of association.

## Dew Apparatus, &c.

The Tress Mercury Vapour Portrait and Printing Lamp. Made by the Tress Company, 42, Oxford Street, London, W.

The Tress Company, which has long made a special feature of incandescent gas lamps for photographic portraiture, has now shown its readiness to supply photographers with a more modern and complete installation of artificial light. The mercury vapour lamp which it is now introducing consists of a three-tube frame mounted on a strong, yet portable, standard, which permits of the lamp being raised to a height of ten feet or lowered to within three feet of the ground, a range which should be sufficient for all ordinary purposes. The outfit is supplied complete with all the necessary accessories, such as plugs and resistances, and even includes a supply of polarity paper for ascertaining that the lamp is being correctly connected in the circuit. From a selection of portraiture made with the lamp, we have every reason to be satisfied with its performance in practice, and the Tress Company very rightly draws attention to the great economy in current from using the mercury vapour system. With the lamp now under consideration, and employing current at the power rate, the cost per hour is frequently only one penny, and may be as low as one halfpenny.

A very excellent feature of the apparatus is the arrangement by which the reflector is secured to the lamp frame. This is done in such a way that the reflector is instantly removable, and the lamp can then be inserted in the printing stand, containing, as usually supplied, eighteen printing frames of half-plate size and three of whole plate, although these numbers can be modified within certain limits to suit the customer's choice. The printing stand is very neatly made, each of the frames being held firmly in position between a rabbit on the side facing the lamp, and a stop on the outside of the stand. The frames, therefore, cannot slip into the inside of the apparatus and accidentally cause the fracture of a tube. Each frame has simply to be sprung into place, and the replacement of the frames when taking off prints is consequently done very expeditiously. The prices of the above excellent apparatus are £8 17s. 6d. for the portrait lamp, tubes, and accessories, and £2 15s. for the portrait stand complete with printing frames—prices which, for the facilities which are offered, are admittedly very reasonable indeed.

THE SWINCAM TRIPOD POINTS.—Mr. William Butler, of 20, Crosby Road, Southport, whose "Swincam" camera stand we were able to review favourably some months ago, is now supplying separately the adjustable tripod points which form a feature of his apparatus. The chief purpose of the attachment is to give stability to a tripod, even when the legs are considerably spread out in order

to secure a low point of view, or for other reasons. Under these circumstances, the small angle between the point of the tripod and the ground on the inside of the leg makes the stability of the stand very slight indeed, and many photographers know to their cost that in such a case the slightest touch will displace one of the legs. Mr. Butler gets over this difficulty very simply by hinging the tripod point so that though the leg itself is at a small angle the point may be exactly perpendicular to the ground. For working in interiors of buildings, and wherever a hard surface is the only resting place for the tripod the attachments should be extremely useful. The tripod, of course, under all other circumstances is at no disadvantage from the attachments. The price of a set of three points complete, with a gimlet enabling the purchaser to fit them, is 10s. 6d.

**The Ever-Full Bottle.** Sold by Messrs. Marion and Co., 22 and 23, Soho Square, London, W.

This piece of apparatus is supplied by Messrs. Marion with the object of obviating the storage of photographic solutions in contact with air, the prejudicial effect of which, particularly upon solutions of sulphite, is universally acknowledged. The principle of the bottle consists very simply in the provision in the bottle of an elastic bladder which can be distended from time to time, as the liquid

is removed, so as to expel the air and bring the fluid contents of the bottle level with the neck. The plug passing through the cork which is seen in the drawing is removable to allow of the solution being poured from the bottle, the glass tube with the flexible connection being employed to expand the bladder in order to make up for the space vacated by the fluid.

**An Enlarger for Wet Negatives.** Made by the Tress Co., 42, Oxford Street, London, W.

A very handy and inexpensive piece of apparatus has been produced by the Tress Company in this newly-introduced enlarger. A

chief novelty of the instrument lies in the carriers. These are made to take negatives of the strip form as used in midjet cameras, or may be obtained to accommodate parts of quarter, or half-plates of the sizes usual in making photographs in repeating backs. In any

case the carrier permits of the negative being placed in focus while in a wet state, and of its being removed without injury. The illumination chamber is provided with an inverted incandescent burner with a reflector which fully illuminates the stage in which the negatives are held. The focussing arrangement is simple yet effective, and the whole apparatus, complete with lens, costs 17s. 6d. It is screwed to the enlarging table, and the sensitive paper or postcard is affixed to any convenient easel or board.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, MARCH 22.

Wakefield Photographic Society. "Enlarging on 'Rotograph' Bromide Paper, including Chat on Toning Bromides."  
Sutton Photographic Club. "Carbon Printing." A. P. Hoole.  
Liverpool Amateur Photographic Association. Opening Reception.  
Cardiff Photographic Society. "The Early Scenes of Christianity in Wales."  
F. Murphy.  
Photographic Society of Ireland. "The Origin of Irish Landscapes." Professor  
Glenville Cole.  
Loughton Photographic Society. "Exposure." L. A. J. Hutchins.

SATURDAY, MARCH 23.

Photo Art Club. Backsburn House.

MONDAY, MARCH 25.

Preston Camera Club. General Meeting.  
Southampton Camera Club. "All at Sea with a Hand Camera." F. J. Mortimer.  
F.R.P.S.  
Gravesend and District Photographic Society. "Ozobrome." A. E. Swift.  
Oxford Camera Club. "Enlarged Negatives on 'Rotograph' Negative Paper."  
Rotary Photographic Company.  
Stone and District Photographic Society. "What can be done with a Hand Camera." C. P. Goetz.

TUESDAY, MARCH 26.

Darlington Camera Club. "Flashlight Photography." R. W. Chapman.  
Redcar and Coatham Photographic Society. "Enlarging on 'Rotograph' Bromide Paper, including Chat on Toning Bromide."  
Hackney Photographic Society. "A Holiday in Wales." F. W. Goelling.  
Royal Photographic Society of Great Britain. "Some Methods of Red Sensitising Estimating Colour Sensitiveness. A Sensitometer for the X-rays." T. Thorpe.  
Baker, F.C.S., F.R.P.S.  
Birmingham Photographic Society. "The Three Colour Process." J. B. Fry.  
M.A., B.Sc.  
Hove Camera Club. "Architectural Photography." V. E. Morris.  
Stafford Photographic Society. "Working-up Enlargements." F. Weiss.  
Keighley and District Photographic Association. Yorkshire Union Portfolio.  
Wallington Camera Club. "Marine Photography."  
Burton-on-Trent Natural History and Archaeological Society. Exhibition and Competition.  
Leeds Photographic Society. "The Story of Fountains Abbey." T. W. Thornton.

WEDNESDAY, MARCH 27.

Everton Camera Club. "Intensification." C. R. Stonehouse. "Sanzol Reduction." W. Tansley.  
Leicester and Leicestershire Photographic Society. "Flower and Fruit Photography." E. Seymour.  
Borough Polytechnic Photographic Society. "A Demonstration of the Gun Bichromate Process." J. C. S. Mummery, F.R.P.S.  
North Middlesex Photographic Society. "The Mansions of Old England." H. Fincham.  
Birmingham Photographic Society. "Spotting and Working-up Prints." Fred Lewis.  
Croydon Camera Club. "The Pictorial Side of Orthochromatism." F. W. Hild.  
"The Development of Colour-Sensitive Plates." E. J. Terry.  
Cowes Camera Club. "Latest Kodak Productions."  
Hartlepool Photographic and Sketching Society. "Enlarged Negatives on 'Rotograph' Negative Paper."  
Edinburgh Photographic Society. "Photographic Odds and Ends." J. Johnston.

THURSDAY, MARCH 28.

Hull Photographic Society. "Photographic News Slides."  
Handsworth Photographic Society. Question Evening.  
Tynemouth Photographic Society. "Enlarged Negatives on 'Rotograph' Negative Paper."

**ROYAL PHOTOGRAPHIC SOCIETY.**—Meeting held Tuesday, March 19, the president, Mr. J. C. S. Mummery, in the chair. A lantern lecture was given by Mr. A. H. Dunning, on "A Year and a half among Savages." On the proposition of the chairman, a hearty vote of thanks to Mr. Dunning was accorded at the conclusion of the lecture.

**PHOTOGRAPHIC SOCIETY OF INDIA.**—The following officials and committee have been elected:—Dr. Pearse, Chairman; Mr. W. J. Simmons and Mr. Aninos, Vice-Chairmen; Mr. E. M. Lane, Hon. Secretary; and Mr. W. J. Oliver, Treasurer. The affairs of the society should prosper in such excellent hands. The date of the annual exhibition has not yet been fixed, but the very excellent display at the Lady Minto Fête showed that the society had not been idle.

**CROYDON CAMERA CLUB.**—In the opinion of all present, by far

the most instructive lecture on "Orthochromatism" ever heard at the club, was given by Dr. Mees on the 13th inst. Although exhaustive in character, it was intentionally elementary in treatment, the general principles underlying the subject being dealt with in a way easily understandable by the veriest beginner. We are informed that the essential features of the lecture will be embodied in a pamphlet shortly to be issued by Messrs. Wray, and doubtless many will be glad to secure a copy.

A capital "One-man show," by Mr. F. W. Hicks, chiefly of marine subjects, executed in plantinotype and carbon, has lately been on exhibition. Mr. Hicks manages to retain in his enlarged negatives the somewhat indefinable and subtle "quality" generally associated only with direct work, and to infuse into his pictures a delightful sense of atmosphere and distance.

**SOUTH LONDON PHOTOGRAPHIC SOCIETY.**—On Monday last Mr. Henry W. Bennett's lecture on "A Visit to the English Cathedrals" was read by the hon. sec. A concise history of English Gothic architecture was given, tracing the development of the various styles from the severe and heavy Early Norman through the graceful Early English to the culminating point in English Gothic. A large number of Mr. Bennett's fine pictorial slides were also shown, illustrating every phase of Romanesque and Gothic architecture.

**EDMONTON AND DISTRICT PHOTOGRAPHIC SOCIETY.**—The Second Annual Meeting of the above Society was held on the 13th inst., the chair being taken by the president, Mr. S. J. Solly. There was a good attendance of members. After the minutes of last meeting had been read and confirmed, and the council's report for the year had been read and adopted, the election of president, council, and officers for the ensuing year took place, when Mr. William Quin was unanimously elected president, and Messrs. Biss, Atkinson, Colville, Bennett, Barnes, Day, Herand, and Holmes, as members of the council; Mr. A. E. Worfolk, as secretary (and treasurer pro tem.); Mr. Solly, librarian; and Mr. H. P. Clarke, lanternist.

After the usual votes of thanks had been accorded to Mr. Worfolk for his past services as secretary, Mr. Solly as past-president, and Messrs. Clarke and Atkinson for their services with the lantern, the meeting was brought to a successful close.

## Commercial & Legal Intelligence.

**CHARGE AGAINST A HULL PHOTOGRAPHER.**—A well-dressed, middle-aged man, named Walter Richards, was committed for trial at Hull on March 14, on a charge of robbing his employer of goods valued at £150. He was engaged as manager for Mr. Charles Wilson, a Newcastle photographer, who has a branch shop in Prospect Street, Hull. Mr. Wilson happened to go to Hull one day, and found his shop empty. Inquiries were made by the police, who discovered that about £100 worth of property had been stored with a shipping company, and another lot had been shipped to London. Richards pleaded not guilty, and reserved his defence. He maintained that the property was his own.

**BARRAUDS, LIMITED, PHOTOGRAPHERS, LIVERPOOL.**—A memorandum of satisfaction in full of a debenture dated November 15, 1905, bearing £300, has been filed.

**ART DEALER CHARGED WITH FRAUD.**—George Samuel Webber, aged 55, described as a fine art dealer, of Portland Road, Hove, Brighton, was charged on a warrant at the West London Court with obtaining money by false pretences. Mr. Pierron represented the accused.

Detective-sergeant Burrell stated that on Thursday afternoon he went to High Street, Rochester, where the accused was carrying on business as a photographic artist, and arrested him on the warrant. He accused made a long statement which the witness proposed to read at the next hearing of the case. He asked for a remand on that evidence, and intimated that there would probably be about fifty cases against the accused.

Mr. Pierron said the defendant had been carrying on business under the title of the International Fine Art Company, and he had over twenty branches throughout England. His business was the enlargement of photographs, and his habit was to allow customers to pay for such enlarged photographs by instalments, the photographs not being delivered until all the instalments had been paid. The only thing that could be brought against the accused was

that in some few cases out of thousands he had not immediately delivered the photographs on the final payment of instalments.

The magistrate remanded the accused, and postponed the question of bail to the next hearing.

**INDECENT PICTURES.**—At the Marlborough Street Police Court, on Tuesday, Henry Stanton Morley, who keeps a novelty bazaar in Tottenham Court Road, W., was summoned for exposing for sale indecent postcards in his shop window, and to show cause why they should not be destroyed. Mr. E. F. Barker prosecuted for the Commissioner of Police, and Mr. Freke Palmer appeared for the defence. Inspector Sewell, D Division, deposed that on the 22nd ult. he went to the shop of the defendant, where he found a number of indecent picture cards exposed for sale. There were several mutoscopes in the place, which had characteristic inscriptions on them, and which, when a penny was placed in the slot, exposed to view objectionable pictures. On one of the machines was written "What Tommy Saw Through the Keyhole," on another "Spoonng in the Park," a third bore the legend, "Matilda's Courtship," and a fourth had written on it "What the Butler Saw." Mr. Freke Palmer: "What the Butler Saw" is the name of a play. Surely there is nothing objectionable in that? (Laughter.) Inspector Sewell: Yes, I think there is in connection with these mutoscopes. Continuing, the inspector said that he seized 1,880 picture cards and 224 slides used in the mutoscopes. Mr. Freke Palmer said the defendant had only had the shop for about six months, and had no idea that he was doing any harm. He purchased the cards from wholesale dealers, and it was they who were the real culprits that should be proceeded against, and not little men like his client. One of the pictures which the police complained of was actually a copy of a well known work by Raffaele. Mr. Denman imposed a fine of £2, with one guinea costs, and made an order for the cards and slides to be destroyed.

## Correspondence.

- \**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*
- \**We do not undertake responsibility for the opinions expressed by our correspondents.*

### BLISTERS ON BROMIDE PRINTS.

To the Editors.

Gentlemen,—Replying to the letter of Mr. A. W. Hutchins, if he puts a handful of powdered alum into his fixing bath and dissolves it properly he will not be troubled with blisters. I have tried it and it has never failed. If omitted, I always get blisters—on bromide postcards particularly.—Yours, etc.,

R. GALLAGHER.

### WEIGHTS AND MEASURES IN THE "ALMANAC."

To the Editors.

Gentlemen,—I have the "British Journal Photographic Almanac" for 1907, and have been reading the formulæ, and am at a loss to understand the weights. In the editorial formulæ, as I understand it, you purport to give English and metric weights side by side.

On page 990, under the head of "Carbon Process," you give "potassium bichromate 1 oz. or 35 to 50 grammes." In the next solution for the same chemical you give 1 oz. or 20 grammes. Then, on the same page, under the head of "Waxing Solutions," you give "Beeswax 20 grains or 10 grammes"; then yellow resin 180 grains or 42 grammes, yellow beeswax 60 grains or 14 grammes, alum 1 oz. or 50 grammes. There seems to be no ratio between the metric and the English weights—in fact, there is the greatest variance—whereas, as I understand it, a gramme is practically 15½ grains.

The metric grammes in your formulæ seem to have double, treble, and six times the value in some places to what they have in others. All the way through the formulæ the same thing occurs.

I shall be glad to know the explanation.—Yours truly,

ROWLAND WM. OSBORN.

Eversley, Hampton Road, Worcester Park, Surrey,

March 16, 1907.

[Our correspondent has fallen into the error which has overtaken many before him. He has failed to notice that though the quanti-

ties in the two sets of measures are not identical the proportion of solids to water is the same in both—that is to say, the solutions have the same composition. He should have done himself the justice to turn back to the head of the section from which he quotes (on page 950), where he will see this fact pointed out. The section also of the "Almanac" dealing with weights and measures commences (on page 1084) with a page-long statement of the conventions adopted in drawing up the formulæ. If these explanations are not sufficient for our correspondent we know of no others which we can recommend to him.—Eds. "B.J."]

#### PROFITS ON PICTURE POSTCARDS.

To the Editors.

Gentlemen,—I am sorry that, owing to pressure of business, I have not had time to look at my JOURNAL, and therefore did not see the query *re* the reasonable price for a photographer to take negatives for wholesale publishers.

This is so often a matter of arrangement between publisher and local photographer, that it is somewhat difficult to answer. At any rate, I consider that 10s. 6d. should be the lowest, that is for either half or whole-plate, for 12 x 10 15s. to one guinea. This is, of course, for a number. If really fine negatives are to be given, and subjects require specially photographing at a definite fixed time, and the higher quality of result is expected, then certainly these prices are too low.

There are plenty of small amateur-professional sort of men who work down to absurd prices, but then their work is equally absurd, too, in quality, badly lit, giving unattractive results, and dear at any price. I find really good work in this direction is not often obtained, and the price so much depends on the actual result. But good work, certainly not less than the prices I name.

Really good work in landscape photography is a very rare commodity, and while some men see pictures everywhere, there are others who call themselves "photographic artists," yet have really very little or no conception of the construction of a picture. First-rate portrait men we have (we might almost say) by the thousand, but good landscape photographic workers are scarce indeed. I am not referring to the amateur-fuzzytype-imitating-gravure-species, aiming at something or other. These are in evidence with their haphazard results at every show. No one takes these fellows seriously.

If each photographic worker would specialise something, if only door-knockers or gargoyles, they might be doing some service, instead of the aimless seeking after "art" so-called, the vain search for which their pictures typify.—Yours faithfully,

FREDERIC T. CORKETT.

2, 3, and 4, Cheapside, City.

March 15, 1907.

To the Editors.

Gentlemen,—In reply to "Professional's" letter in your last issue asking for an interpretation of a clause in my last letter *re* a professional friend "selling real photographic postcards from whole plates" and "exposing the cards in the camera, giving fifteen minutes' exposure," and "pleased to get threepence each for them."

It seems to me it is he ("Professional") who clearly places himself on a level with your correspondent who wanted "an apparatus for taking, developing, and fixing Daguerreotypes in one."

I purposely refrained from any attempt at literary style in my letter, and I do not see how it could be more plainly put. Can it be possible that "Professional" never heard of small prints being made by that process known as reduction in the camera from large plates direct on to bromide or postcards?

It does seem so ridiculous for any photographer to do any such thing, and is only equalled by "Professional's" ignorance. I hardly think it necessary to take up any space explaining how it is done, as the merest amateur could explain it to him. However, if "Professional" persists in his ignorance I shall be pleased to explain in another issue.—Yours,

POSTCARD.

#### THE STABILITY OF PYRO AND SODA DEVELOPING SOLUTIONS.

To the Editors.

Gentlemen,—In a previous letter on this question (B.J. 1906, October 19, p. 837), I showed that the action of sulphite in the developer was not that commonly assumed, viz., of an oxygen

devourer, but that the sulphite and organic reducer exert a mutual protective action depending on a complicated cycle of reactions. In studying with quite other views the literature of phosphorescence recently, I came across an independent confirmation of the view expressed, based on quite different grounds. The reference is to the well-known work of P. Lenard and M. Wolf on the luminescence of pyrogallol acid (Wied. Ann. 1888, 34, 918-925). Pyro developer poured into alum solution gives a well-marked phosphorescence. The developer consisted of pyro, carbonate of potash and sulphite. L. and P. showed that precipitated oxide of aluminium condensed oxygen on its surface which rapidly oxidises the pyro. Oxygen dissolved in the solution, is necessary for the reaction, and the remarkable result was obtained, that a developer containing sulphite has more free oxygen dissolved in it than one without. Their words are, "Why a substance such as sodium sulphite, well known to absorb oxygen rapidly, should be necessary to the luminescence, appears a mystery. Sulphite is used to make the pyro solution keep, as we imagined, by virtue of absorbing all the oxygen which enters the solution, so keeping the pyro from reacting with this. But in this case a developer freed by sulphite from oxygen should be incapable of luminescence." In fact, the reverse was found to be the case, and in view of its peculiar action, the only assumption tenable was that "a mixture of water, pyro, sulphite and carbonate—for brevity, pyro-sulphite-alkali—uses up oxygen less rapidly than pyro-alkali alone." The only hypothesis in explanation which could suggest was that the sulphite possibly exercised a disinfectant or antiseptic action by poisoning micro-organisms which might assist the oxidation of the pyro. This, however, as my former letter showed, is neither sufficient nor necessary.—I am, yours, etc.,

Marburg-a-L., Germany.

S. E. SHEPPARD.

#### THEATRICAL PHOTOGRAPHY.

To the Editors.

Gentlemen,—I was much interested in the article, "Theatrical Photography," appearing in the Journal of March 8, and having tried and failed some considerable time ago, I thought of "desperandum," and tried again. This time I have pleasure in sending you my result. The plate used was an extra special "Roy Standard," bathed in pinachrome 1-1,000 for three minutes, and washed about five minutes. This was then put in the slide and

exposed in a wet condition in the evening. It was taken with a stand camera, full aperture of lens, cap on and off very quickly, from the back of dress circle during the performance, and there was a very fair amount of light on the subject. The developer was metal hydroquinone, given with the make of plates, and the light used in development was a red and green glass in front of light (lamp). The exposure was made at the end of sketch, entitled "The Stowaway."—Yours faithfully,

H. EDWARDS

102, Leytonstone Road, E., March 12, 1907.

[The print is a very fair example, we think, of a stage photograph.—Eds. "B.J."]

#### BUSINESS METHODS IN THE STUDIO.

To the Editors.

Gentlemen,—I am glad to find that the method of keeping a tabulated cash book, which I published in my little book on "P

essional Photography" about four years ago, has proved useful to your contributor, Mr. S. E. Kaye. Reference to page 58, Vol. I, of the book I mention will show the specimen page I gave, that of Mr. Kaye in your current issue being in detail almost an exact counterpart. The method enables a business photographer to see at a glance what he is spending in any particular direction, and what he is himself drawing from the business, and the information is obtained without any posting up of a ledger from day-book entries, thus simplifying the account book-keeping and saving much, often being postponed, work.—Yours, faithfully,  
C. H. HEWITT.

309, Regent Street, W

[The columnar form of cash-book is one that is generally known, and is in frequent use. Our contributor says that he has used it for fifteen years, but that he does not claim to have originated it as, we make it, does Mr. Hewitt. Writing in "The American Business and Accounting Encyclopædia," F. H. MacPherson, C.A., says "Below a form of cash-book to be used when all receipts are paid directly into the bank and where payments are made only by cheque. . . . if it is considered desirable to introduce the columnar system into this form of cash account, and I favour its use at all times and in every conceivable place, to save labour, the necessary columns can be inserted."—Eds. "B.J."]

To the Editors.

Gentlemen,—It was with great interest that I read in this week's journal the article on "Business Methods in the Studio," by S. E. Kaye. I am confident it will be a great help to many who up to this time have paid little attention to book-keeping as long as things sail along clear.

Do you know of any business house that can supply the books you speak of, if such could be obtained it would be a further help and save a lot of time.—Thanking you in anticipation of a reply through the columns of your valued journal, I am, yours faithfully,  
W. H. DEE.

310, King's Road, Reading.

[Walter Pearce, and Co., of St. George's Press, Brentford, will naturally have a set of books on sale.—Eds. "B.J."]

#### ENCLOSED ARC FOR PORTRAITURE.

To the Editors.

Gentlemen,—Re enclosed type of arc lamp, you had a note re above in reference to enlargers, that enlargements, although focussed sharply on the screen, were not sharp when developed; this I can bear out in my own practice, but I have not seen it mentioned that the same peculiarity exists when taking sitters in the studio with this type of lamp—at least, I have found it so with the lamp I am using (a 15 amp. Jandus enclosed arc lamp). I have had this lamp installed about three months, and at first I could not understand that none of the negatives taken were sharp on the figure, but always critically sharp on the background, like it used to be with the old type of lenses where the chemical and visual focus were not coincident, so I made several experiments to see if it was really so, that the focus was altered when using this type of lamp, and I proved absolutely to my own satisfaction that it was so. I have taken several negatives demonstrating this, which I can send you if you consider the subject worth discussing. I have taken figures singly and in groups, focussing the figure absolutely sharp with a Dallmeyer compound magnifier, exposed the plate and then another one on the same subject, same position, etc., but focussed slightly inward, showing under the magnifier a soft out-of-focus effect. When developed the first one would be out of focus on the figure, and the background sharp; in the second the figure was sharp and the background as it should be, in fact, just as the first one was focussed. This, you must know, makes it very awkward in a studio where one uses daylight during the day and electric light at night for late appointments, etc., as the focussing has to be different in each case. I think the subject is worth discussing in your excellent journal. I have been a reader of it for over 25 years, but never before have I written you on any subject; only the thought that this matter ought to be probed to the bottom tempted me to write now.—Yours very sincerely,  
A. COURE.

[We shall be glad to see the examples offered, and will deal with the subject more fully ere long.—Eds. "B.J."]

## Answers to Correspondents.

- \* All matters intended for the text portion of this Journal, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, &c. Two unmounted copies of each photograph must be sent with the fee.

#### PHOTOGRAPHS REGISTERED:—

- F. Nainby, Challoner Street, Cokermouth. Photograph of the meet of the Coker-mouth Beagles at Butterworth.
- R. Thirlwell, 21, Bridge Road, Stockton-on-Tees. Two Photographs of railway smash, Thornaby-on-Tees.
- E. Kelley, 26, Queen Street, Newton Abbot, Devon. Photograph of the Newton Abbot Rugby Football 1st and 2nd teams, with members of Committee. 1906-7.
- F. Marshall, 10, Bridge Street, Blaydon-on-Tyne. Photograph of Messrs. J. Hewitt, J. Hoger, and J. Anderson, all of Blaydon. Photograph of Mr. and Mrs. J. Carr, Thomas Terrace, Blaydon-on-Tyne.
- J. W. Tattersall, 55, Avenue Parade, Accrington. Photograph of the Rev. C. Williams.

BOOKS.—Will you kindly advise me in the choice of text-books upon the following subjects:—1. The chemistry of photography. 2. The collotype process. I want to know the best book (or books) upon each subject. The books may be printed in English or German. 3. Also could you tell me the name of a publisher of German books who would supply me with a list of German photographic publications?—BOOKS.

1. Valenta's "Photographische Chemie," or Meldola's "Chemistry of Photography." The two books are very different in character.
2. "Der Lichtdruck," by August Albert, or "Practical Collotype," by A. W. Fithian.
3. W. Knapp, Halle a/S, or Gustav Schmidt, Berlin, W., 10.

"JANDUS" LAMPS.—Will you kindly inform me the address of the "Jandus" Company, makers of "Jandus" electric arc, for portraiture?—E. F. SANDERS.

Messrs. Drake and Gorham, Victoria Street, London, S.W.

W. WASHAM.—The anti-halation sheets are obtainable from Messrs. Butcher and Sons, Camera House, St. Bride Street, E.C. We have seen formulæ for making such sheets, consisting of gum, caramel and sienna, but we have never attempted to make them. We suggest you obtain a large size and cut down to one size of your plate. Except for very difficult subjects, the pads are almost equal to a good packing.

TITLES ON POSTCARDS.—Could you please tell me how the titling of enclosed postcard is done, and what kind it is?—JOHN STEELE.

The words of the title are set up in type and photographed on a slow or photo-mechanical plate. The strip containing the line of lettering is then cut through to the glass and stripped off with hydrofluoric acid, or other means, on to the postcard negative, which in some cases requires no preparation to receive it, but in others needs to have a strip of similar size cut from it.

J. E. (Edinburgh).—We have no recollection of a roller-blind apparatus; but, assuming that it exists, your device, we should say, would be no infringement of it. The two methods are surely quite distinct, although it would, of course, be possible to frame a specification which would clash with that of the roller-blind apparatus. But we gather that is not your intention, and, so far as we can judge, your method is distinct from the one to which you allude.

BUSINESS IN THE STUDIO.—May I ask if there are such books, as are mentioned in your article on the above topic, to be obtained from firms who supply professional photographers, such as Fallowfields, Marions, or Houghtons, etc.? If not, would it not be advisable for such firms to prepare these, for the especial use

of professional photographers. I shall be glad to hear where they are to be obtained now.—RUTTS.

So far as we know, there are only the usual manuals of book-keeping issued by the Pitman Metropolitan School and similar institutions. The only photographic work which deals at all with the business aspect of the studio is "Professional Photography," by C. H. Hewitt. (Hiffe, two volumes, 1s. each.)

**COLOURING PHOTOGRAPHS.**—Would you kindly inform me of a book dealing with the colouring and working-up of photographs, and where it may be obtained?—J. S.

The only book is "Retouching Photographic Negatives and Prints," by Johnson, published by Marion and Co., at 2s. 6d. The recent articles in our columns on working up with the air-brush have been republished by the Aerograph Company, 43, Holborn Viaduct, London, E.C., at 6d., and constitute the best guide to the use of that instrument.

**CHEAP ENLARGEMENT.**—I have a customer who is inquiring for a cheaper class of enlargement than can be turned out on bromide paper. He speaks of a paper which he calls "salted" paper. Of course, I quite understand what ordinary salted paper is, but that would be no use for enlargements. Do you know of any other kind of paper besides bromide which can be used for enlargements?—H. AND CO.

We gave the formula for the class of paper your customer refers to in our issue of March 30, 1906, p. 246.

**FINISHING ENLARGEMENTS.**—Can you tell me where I can obtain a book upon finishing and working up enlargements in black and white, with crayon and brush, instructions how to prepare the varnish, or other preparation, which has to be sprayed or brushed on, to fix the crayon work, so that same does not rub off, and yet show an even surface on the finished enlargement?—NEMO.

The only book is "Retouching Negatives and Prints," by R. Johnson (Marion and Co., 2s. 6d.).

**TRAVELLING STUDIO.**—I have thought of having a travelling studio bought for going round amongst the villages here in the summer time. What size would you recommend for same? Of course, I suppose it would be better to be on wheels, and one that would be large enough for groups. Give any particulars you think proper for lighting of same, etc. What would be the cost of building complete—I mean for a good thing? There would be some difficulty in getting water. What would you recommend to overcome the difficulty?—G. T.

We should advise you to purchase a caravan and take in it a portable studio, which you can erect at stopping places. Messrs. Marion, 22, Soho Square, supply a studio of this kind, and you can usually obtain a caravan through a small advertisement in our columns.

**COLLODION EMULSION.**—I would be very pleased if you could supply me with the formula for the making of a collodion bromide emulsion and working of same. It is used for photographing on boxwood for engraving purposes.—A READER.

You can employ almost any of the emulsion formulæ given in the "Almanac" for 1907, page 978.

**FOCUSsing SCREEN.**—I have reason to believe that the focussing glass in my studio camera is not in proper register with the plate. Could you please let me know the way to remedy this?—OLIVER T. R. THOMPSON.

The only way is to have the rebate of the focussing screen altered. You can find out by placing a ground glass in the place of the plate in one of the dark slides, whether the focussing frame requires packing or thinning. We should think that in any case it will be best to send the camera back to the makers, or to a repairing firm, such as A. B. Allen, 20, Endell Street, London, E.C.

**SULPHIDE TONING.**—(1) Can you inform me, through your valuable paper, if you know of a formula for sepia toning of bromides by sulphur with three solutions—i.e., 1, which makes the positive look negative; 2, bleaches; 3, tones? (2) Also, is there any preservative for pyro which can be added to any standard formula?—SEPIA BROMIDE.

(1) There is a number of well-known formulæ and a number of preparations on the market sold as sepia or sulphide toners. As good a formula as any is given in the "Almanac," 1907, page 988. Two solutions are used—a bleacher of ferricyanide

and bromide, and a darkening or toning solution of sodium sulphide. You appear to require an elementary book on toning processes, such as "Toning Bromides," by C. W. Somerville (Dawbarn and Ward, 1s.). (2) None better than potassium metabisulphate.

**ARCHER CLARKE.**—Each must be separately registered to secure copyright in each. Proofs from the zincos may be deposited Stationers' Hall.

**"SPRING CLEANING."**—A blue-grey. The ingredients for a distemper colour are the same as given in the article on background painting, p. 81, of our issue of February 1, to which we refer you.

**SILHOUETTES.**—Will you kindly tell me how the photographs popularly termed silhouettes are done, and oblige.—COUNTRY.

The figure is placed against a thin white background lighted from behind, and a good deal less than a proper exposure given on a fairly slow plate, which is afterwards developed with a strong restrained developer—say pyro soda with three grains of pyro. If a full-length figure is required in silhouette, a table on platform must be provided for the person to sit or stand on, the lens being placed on a level with the feet. Except by this dodge the feet of the model are merged with the floor in the silhouette.

**COLOUR FILTERS.**—In the "British Journal Almanac" for 1905 Mr. George T. Harris, F.R.P.S., refers to a formula given in your "Almanac" for 1893 for making colour filters, to use for landscapes with orthochromatic plates. As I was not then a photographer, I do not possess the "Almanac" for that year, but should like to know the formula. I have to give a demonstration on home-made filters, and if you have one or two different methods I should be very much obliged if you would give them to me.—J. SHEPHERD.

Mr. Harris's method was as follows:—A piece of glass was prepared with beeswax, as if for enamelling, was coated with a solution of gelatine, and put aside in a place free from dust for the gelatine to set. The gelatine solution was a 20-grain-per-oz. solution of Heinrich's hard. The plate was then immersed in a 5-grain-per-oz. solution of ammonium picrate, dried, and the film then stripped off. It is more usual now to stain the gelatine solution first, and apply a measured quantity to a given area of glass. Recent issues of the "Almanac" have contained a good deal of information on the subject, and perhaps it would also be to your advantage to study "Practical Orthochromatic Photography," by Arthur Payne (Hiffe, 1s.).

**EXAMINATIONS.**—I am an assistant operator, but would like to improve my position, if possible. I am well up in photography, both practical and theoretical. Are there any exams. in photography for which I could sit?—S. T.

The secretary of the City and Guilds of London Institute, London, will send you particulars of the Institute's examinations, which are held in April annually, and for which you will be too late this year. The students' Fellowship application arrangements of the Royal Photographic Society (the Secretary, 66 Russell Square, W.C.) may be of use to you; and you might write to the Professional Photographers' Association (89, Albany Street, London, W.) for particulars of their "Certificates for Assistants" scheme.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The remarkable tanning action of quinone on gelatine has been examined by MM. Lumière, who are unable to prove the existence of a compound of gelatine and quinone. (P. 232.)

Mr. C. Welborne Piper draws attention to the importance of the theory of the objective plane in modern optics. (P. 235.)

We quote the results of a number of experiments, which should discount the statement sometimes made as to the danger of storing celluloid. (P. 231.)

The directions of an American writer for the wash-colouring of photographs are given on page 234.

The Northern Exhibition opened at Liverpool last Friday has proved a notable success. The catalogue is as fine a production as we can recollect. (P. 241.)

Business Management. The concluding hints on the elements of business system for photographers appear on page 233.

A German writer has supplied a comprehensive review of the facts in raw paper, many of which may affect the manufacturer plain or emulsion papers. (P. 236.)

Proposed reforms in the Patent Law of Great Britain will undoubtedly benefit the photographic inventor. (P. 220 and 240.)

The compulsory adoption of the metric system was defeated in Parliament last week. (P. 230.)

Royal Photographic Society. The committees responsible for the management of the different departments of the society are given on page 240.

## EX CATHEDRA.

### The German 1909 Exhibition at Dresden.

We have received a circular from what we take to be the municipality of Dresden giving the full scheme of the international photographic exhibition, which, as we have already announced, it is proposed to hold in Dresden in the year 1909. The full text of the programme may be epitomised by saying that the exhibition will consist of four great sections, the first devoted to the history of photography, and to the present facilities which exist through the press and in schools for instruction in photography. The theoretical aspect of photography and colour photography will be included in this section, although to our ideas of classification they appear somewhat out of place. In the second class professional and scientific photography and reproduction processes will form the chief features; and classes 3 and 4 will be devoted respectively to amateur photography and the photographic trade. We hope to give some further particulars of the scheme as soon as we have information of the committee who have been appointed to make the preliminary arrangements.

### Patent Law Reformers.

A Bill to amend the law relating to patents and designs was introduced in the House of Commons one day last week by Mr. Lloyd-George. This Bill, if carried into law, is of interest to the large number of photographic inventors who, as our columns testify each week, apply to Southampton Buildings for Royal Letters Patent. There is no question that our patent law, as it now stands, presses heavily on British inventors. If they patent their inventions in almost any foreign country they are bound to work their invention in that country. But if a foreign inventor patents an invention here he is under no such restriction; he gets his monopoly, sends the manufactured articles to us from abroad, and English industry suffers accordingly. Hence the law allows a foreign inventor to bind British enterprise hand and foot on its own soil. The foreign patentee does not set up works here, but he prevents any British subject from taking out a similar patent. And the injustice of the position is greater still when, as is not infrequently the case, the foreign patent is drawn up in such a comprehensive way as to include processes which obviously are impracticable, yet from their inclusion in the specification may not be adopted by another inventor.

### Unworkable Patents.

In illustration of the patent which is merely a patent, and not a process, it would not be difficult to cite many instances, particularly among recent chemical specifications. For example, to select one from photography, it was not many years ago that a patent was granted for a process of pigment printing

involving the use of ferric salts and formaldehyde. The action of the process was to have been as follows:—Gelatine films containing both the two above substances and a pigment were exposed to light, with the result that where the reduction of ferric to ferrous salt took place the formaldehyde would become oxidised, and the gelatine, which was previously insoluble, would become soluble. That process, in our experience, has never been practically worked; certainly it has never been on the British market, yet any inventor who succeeds in making it workable will find this patent against him in his efforts to 'exploit the invention. The reform which it is to be hoped will speedily become law will be welcomed by almost every class in the community whom it concerns.

#### Deposition of Samples.

This evil of super-comprehensiveness the proposed Bill is also to remedy. At present many of the foreigners' patents relating to chemical substances, taken out here, are so worded that they not only cover the discovery really made, but also every other which human imagination is able to conceive. In the new Bill this is remedied, as the applicant for a patent will have to deposit samples of the chemical substance for which the patent is granted. Another point in the Bill is of importance. At present it is very usual when a licence is granted for working a patent, particularly under patents taken by foreigners, to make it a condition that the licensee works no other process or makes no articles by a process acquired from any other person. A condition such as this in the licence will, according to the Bill, become null and void. So far as we can see, the Bill, as framed, if it passes into law, will be of great benefit to English inventors. It is proposed that the amended Act comes into force on January 1 next.

#### The Metric System in Parliament.

The hopes of the advocates of the compulsory adoption of the metric system of weights and measures had a decided set-back last week. On Friday last Mr. Strauss moved, in the House of Commons, the second reading of the Weights and Measures (Metric System) Bill. Previously, this Member had presented a petition, signed by over 16,000 persons in various trades and callings, in favour of the Bill. During the discussion it was mentioned that, with the exception of England and Russia, the metric system was in vogue in all European countries. It was admitted by the opponents of the Bill that our present system was complicated and unsatisfactory, but that any compulsory change at present was undesirable, in view of the fact that at present the use of metric weights and measures is legalised. The President of the Board of Trade, who had received deputations from both sides on the question, in his speech, said in effect that when the various trading interests in the country were agreed amongst themselves as to the necessity of making a compulsory change in the weights and measures, it would be time enough to consider the matter in Parliament. In the end, the motion for the second reading was rejected by a substantial majority; so the matter remains shelved for the present, in spite of the great activity of the Decimal Association. It may be mentioned that the United States is not in favour of the metric system, for last year Congress threw out, for the fourth time, a Bill to render the metric system compulsory.

#### Unsuspected Causes of Defects.

Whenever our advice is asked in regard to photographic materials which are alleged to give rise to defects beyond the control of the user, our first recommendation is that a supply of the defective material be sent to some friend

or colleague of the complainant who has an establishment totally distinct from that in which the unfavourable results have been obtained. The quite separate use of the plates or papers by one who understands their treatment has frequently led to the production of perfectly faultless results, and proof positive has been afterwards afforded that the cause of all the trouble was a minor matter unsuspected under the worker's very nose. A case in point which was settled in this way may be mentioned. A photographer had recently obtained a stock of plates every negative from which was more or less marked with black spots: sometimes with one or two only, but on other occasions the spots appeared in numbers. After endless speculations a brother worker in another town, whom some of the plates were sent, returned a batch of negatives without a single defect of the kind. The cause which was thus located at home, eventually turned out to be a dusting brush which at some previous time had been used for sensitising with an iron solution, and had retained minute particles of iron salt, which, in conjunction with the pyro developer, had led to the plague of spots.

#### Spring Actinism.

The calendar tells us that this is spring, but the country, so far as vegetation concerned, does not confirm the assertion; yet the more reasonable weather we have had during the past week, so, if it continues, will, no doubt, soon alter the appearance of things out of doors. Be that as it may, however, the light of late has greatly improved in quality from what was a month ago, and novices should realise the fact or they will be greatly over-exposing their plates. Frequent showers between April showers, if the sun is shining, the light is far more actinic than it is at midsummer, and as the shadows are longer the light is more diffused. Hence shorter exposures are required than when the sun is near the zenith. This fact is often overlooked, or not recognised by the inexperienced in outdoor photography.

#### Chrome Alum.

Some years ago chrome alum was much more discussed as a substitute for the better-known alum in which the metal aluminium is present as the metallic base, but nevertheless the properties of the chromium compound are such as should not be overlooked. In particular the use of chrome alum as the final hardening bath in the treatment of gelatino-chloride prints is not as well known as it deserves to be, inasmuch as a much weaker solution may be used, and the bath free—or perhaps we should say may be free—from the acidity which, in the case of ordinary alum, acts prejudicially upon the permanence of the prints. It is only necessary that we should mention the means which can be taken to secure the proper condition of the chrome alum. Any excess of acid in it may be removed by powdering the crystals and treating the powder with methylated spirit in which the alum itself is quite insoluble, but by which any acid impurity is removed.

"THE MOVING PICTURE WORLD."—We have received the first number of a new weekly publication issued under the above title from the World Photographic Publishing Company, 361, Broadway, New York. It is a journal of the cinematograph and lantern-slide trade, and is edited, we see, by Mr. Alfred H. Saunders, who will be remembered, perhaps, by readers in Birmingham as having for a short period been responsible for the appearance of that fully-titled publication "The Optical Magic-Lantern Journal and Photographic Enlarger." The issue before us contains an article by the producer of song slides detailing the heroics which must precede the completion of a set of slides illustrating such sublime themes as "Linda, Can't You Love Your Joe?" or the child scene "Hello Central, Give Me Heaven." These songs, we read, are in great demand amongst the places of entertainment.

## EXPERIMENTS ON CELLULOID.

One important has become of late years the use of celluloid in the manufacture of sensitive materials that any facts or accredited information with regard to its keeping properties deserve the careful attention, not only of those who actually undertake the manufacture of the articles, but also of others who have to store the manufactured product in greater or less quantities. Technical information on celluloid being as a rule jealously guarded by the comparatively few firms who undertake its manufacture, more than usual interest may attach to some accounts of experiments by Dr. Will, which, through the kindness of a friend associated with the industry, have been placed at our disposal. Although the points to which we refer below have been considered chiefly in regard to the frequent fatalities which have occurred from the combustion of celluloid manufactured for articles of ornament or adornment, yet the ascertained facts may reasonably be held to apply approximately to any mixture of nitro-cellulose and camphor. The former compound is, of course, the constituent of the celluloid which is sensitive to shock or friction, although its dangerous proclivities are greatly minimised by its admixture with the camphor. Yet it has been proved that the effect of heat on nitro-cellulose increases in a high ratio as the temperature rises, and becomes, so it has been estimated, about four times its original quantity for every rise of 10 degrees Cent.; and the camphor, although it has a restraining effect on the decomposition, yet has no absolute control of this liability to decomposition.

In regard to the factors which may lead to the ignition, often alleged to be spontaneous, of celluloid, an important one is its behaviour towards shock after keeping. It has been found, however, that the "falling-weight" test, in which the steel surface of a 2,000-gm. weight falling 2 yds. on a fragment of celluloid was attended by no explosion, supports the view that the liability of celluloid to inflame from such a cause may be considered negligible. Equally, celluloid has been found, in the recent experiments to which we are now referring, to be indifferent to the electric current and to sparks. It was found impossible to ignite celluloid a few tenths of a millimetre in thickness by means of Leyden jars and induction machines. Cases are upon record of the inflammation of celluloid having taken place through these means, but explosion from this cause is apparently unknown. In regard to the behaviour of celluloid towards heat, it has been found that the material, skilfully prepared, comes to no harm when stored in the neighbourhood of ovens, heating pipes, electric lamps, etc., such as are likely to be met with under ordinary conditions; yet either badly made or deteriorated samples possess much less immunity to an elevated temperature than is indicated by the above general statement, and it is from this cause, probably, that the numerous fires from celluloid have arisen. The two causes of such easily-ignitable celluloid are an inferior stability of the nitro-cellulose used in the manufacture, or the deterioration of the product by the use of too high a temperature in its after-treatment. As photographic celluloid is exposed to a temperature very

little higher than that of the air, the latter factor need not be considered.

In regard to accidents from celluloid in a state of combustion, Dr. Will has found it well to distinguish between a true explosion of the celluloid and the ignition of mixtures of air with the gaseous decomposition products of the celluloid. It was found that in the direct combustion of celluloid no explosion was obtained unless the products of decomposition were mixed with air and ignited. These decomposition products differ greatly in composition according to the circumstances under which they are produced, and pressure particularly is a factor in the case. In one series of experiments it was found that the gas contained 45 per cent. of carbonic oxide, 19 per cent. of methane, and 10 per cent. of hydrogen, the other constituents being nitrogen and carbon dioxide, 9.6 and 14.7 respectively. From experiments made under different conditions of pressure, it appears to be highly important in the case of a celluloid conflagration to limit the air supply, and the most suitable means, therefore, of treating a conflagration consists in the use of water and moist sand, applied to the mass of the celluloid itself. Grenades containing salts or salt solutions are of little use.

Other experiments on the resistance of celluloid to heat confirm the general conclusions which have been summarised above, and stress is laid upon the importance of the quality of the celluloid as affecting any accidents which may occur as the result of its storage. A properly prepared sample may be safely housed in conditions which would be dangerous to an inferior product. A very safe criterion of the quality of a sample of celluloid is the "fuming off" test, which consists in placing about one-tenth of a gram of small pieces of celluloid in a stout, lightly corked test tube, which latter is immersed in an oil bath heated to 100 degrees Cent. The bath is kept uniformly heated by means of a stirrer, and heat is slowly and regularly applied, so that the temperature of the oil bath rises regularly about five degrees per minute. The temperature at which the sample commences to emit fumes is noted, and its lowness is characteristic of badly manufactured celluloid: 160 degrees Cent. may be taken as a limit below which celluloid may be considered unsuitable for storage. The danger associated with the storage of celluloid, so we may conclude from the information before us—information which, we may say, is the result of the widest technical experience in the handling of celluloid products—is quite trifling provided that the ordinary conditions of safety are observed, and so long as a product giving a satisfactory fuming-off test is obtained. Celluloid, of course, like any other combustible substance, becomes ignited in contact with a flame; and, as already mentioned, the gases which it then evolves may lead to the formation of an explosive mixture. Moreover, in the case of celluloid which burns with an insufficient supply of air, the gaseous products may be of such a poisonous nature as to entail loss of life to persons near at hand, inasmuch as hydrocyanic or prussic acid may then be a constituent of the gases. Those having occasion to cut, turn, or otherwise treat celluloid with cutting tools should also be cautioned that the celluloid dust may itself form an explosive mixture with air.

ROYAL PHOTOGRAPHIC SOCIETY.—The council have elected the following to be honorary Fellows of the society: Mr. Vero C. Driffeld, for his work in connection with the measurement of photographic rates, and Mr. R. H. Bow, for his researches in optics.

MESSRS. J. LANCASTER AND SONS, LIMITED.—Those who have been familiar for many years with Messrs. Lancaster's establishment in Colmore Row, Birmingham, should make a careful note of the

fact that the growing demands of the business for space have now compelled the firm to take larger and more convenient premises, which they have at length found at 275 Broad Street, Birmingham. All inquiries should in future be sent to this address. On a recent visit we were able to see the very effective means which Messrs. Lancaster have taken in their new home to deal with their worldwide trade in cameras and other photographic apparatus.

## THE TANNING OF GELATINE BY SOLUTION OF QUINONE.

We have already shown that ordinary quinone is capable of rendering gelatine insoluble in warm water. This insolubility may be obtained by causing the quinone solution to act not only upon solid gelatine, but also upon solutions of it. This property of quinone is the more remarkable because up to the present, among definite organic compounds, only one substance endowed with similar qualities has been known, viz., formaldehyde. We propose in the present treatise to determine the best conditions for the insolubilisation of gelatine, both solid and in solution. We have endeavoured, on the other hand, to determine the composition of gelatine insolubilised by quinone under various conditions, in order to find if this composition is constant, and if "quinonised" gelatine may be considered of definite composition.

### I.

We mixed a fixed amount of gelatine solution of strength of from 5 to 20 per cent. with an increasing quantity of quinone solution of  $\frac{1}{2}$  per cent., and when all solutions had set we examined those which did not liquefy again in the heat. The smallest quantities of quinone which appear necessary to render gelatine insoluble in hot water after it has set are the following:—

Solution of gelatine, 5 per cent. 4 gms., 10 per cent. 1 gm., 20 per cent. 1 gm. of quinone to 100 gms. of dry gelatine.

The solutions thus obtained are not precipitated, they are clear, reddish yellow in colour, and solidify in almost the same time as required for the solidifying of the original solutions of gelatine without the addition of quinone.

Once solidification is complete the jelly cannot be liquefied again, even at 100 degrees, and the product thus insolubilised retains that property even after a prolonged immersion in water.

With 1-1,000 solutions of quinone sheet-gelatine may be rendered insoluble by employing about 1 litre of quinone solution to 20 grammes of gelatine; but in this case a long time is required to obtain insolubilisation.

This time may be greatly shortened if a more concentrated solution is used. Thus, when using 1 litre of 4 gms. strength the insolubilisation of 20 gms. of gelatine at a temperature of 15 degrees would take  $1\frac{3}{4}$  hour, but only  $1\frac{1}{4}$  hour would be necessary if the strength of the solution were 6 gms. a litre.

The more diluted the solution of quinone used, the less coloured is the gelatine treated with it.\*

### II.

To determine the quantity of quinone which a given weight of gelatine requires to cause it to become insoluble in water we have considered the possibility of recovering, on the one hand, gelatine, on the other, quinone, from the quinone-treated gelatine, a work suggested by our former labours with formalised gelatine.

To this end we have treated the insoluble gelatine with acids, with alkaline carbonates, with ammonia, and with caustic alkalis, of varying degrees of concentration and temperature. With not one of these re-agents have we succeeded in recovering gelatine and quinone. As soon as the gelatine became once more soluble in warm water it was disintegrated. In no case could the presence of free quinone in the solutions be distinguished.

Quinone-treated gelatine, therefore, appears to possess greater stability than formalised gelatine. Moreover, it is not affected by repeated immersions in boiling water, as is formalised gelatine—it seems rather to be a combination of a simple

\*The watery solutions of quinone alter by degrees on exposure to the air, and solubility in cold water being very slight (0.5 per cent.), it is better to use quinone in the form of alcoholic solution, say 5 per cent. It does not precipitate when water is added. If this solution has been prepared with decomposed quinone it will be a brown colour; it can be considerably cleared by shaking it up with animal black.

additive compound, but we have not yet succeeded in establishing the method of its formation. In order to determine the composition of this substance remains the same, when gelatine in various states of dilution is treated with an excess of quinone we have insolubilised sheets of gelatine under the two following conditions:—

(a) 100 grammes of sheet gelatine in 5 litres of solution containing 4 grammes of quinone to the litre.

(b) 100 grammes of sheet gelatine in 5 litres of solution, containing 1 gramme of quinone to the litre.

After twelve hours' contact the sheets of gelatine were washed in running water for twenty-four hours, and pressed every half-hour to eliminate all excess of quinone.

The drained sheets were dehydrated with alcohol, dried at 100 to 110 degrees, and then submitted to elementary analysis. The insolubilised gelatine in case (b) was more lightly coloured than that in case (a).

The analysis of these two varieties of quinone-treated gelatine led to approximately the same percentage composition.

The result of these analyses is as follows:—

Elements in 100 gms. of Gelatine.	a. Gelatine Insolubilised with excess of Quinone.			b. Gelatine Insolubilised with Insufficient Quinone.			Ordinary Gelatine not Insol.
	Analyses.			Analyses.			
	1	2	3	1	2	3	
Carbon .....	51.62	51.8	51.5	51.43	51.2	51.4	50.9
Hydrogen .....	6.32	6.5	6.6	6.35	6.50	6.55	6.4
Nitrogen .....	17.56	17.64	17.49	17.63	17.42	17.54	18.3
Oxygen .....	24.5	24.06	24.11	24.42	24.88	24.51	23.2

These results merely show that the percentage composition of the gelatine after its insolubilisation by the quinone has been greatly modified, and that it seems to be invariable however great may be the excess of the quinone employed. One can hardly decide anything as to the quantity of quinone necessary for a given weight of gelatine, but it is probable from what have been seen above that it is but small.

### The Properties of Quinone-Treated Gelatine.

Gelatine prepared with a solution of pure quinone is a more rose colour in a thin film and reddish brown in a thick film. This coloration soon appears in the quinone solutions of clear yellow colour in proportion as the gelatine becomes insoluble, and without the presence of oxygen being necessary. The colour of the quinone-affected gelatine is, therefore, dark in proportion as the quinone solution is coloured. It may be reddish-brown. The quinone-treated gelatine swells in cold water, but notably less so than formalised gelatine. It is soluble in hot, even boiling water, and does not swell appreciably more in warm water than in cold. It is highly stable and its insolubility persists even after protracted boiling—an order which formalised gelatine will not pass through unaltered. When it has swollen in cold water it is elastic, and offers great resistance to tensile strain, but on drying it becomes as brittle as formalised gelatine.

The quinone-treated gelatine cannot be broken up into gelatine and quinone by acids, caustic alkalis, carbonates, or ammonia. Acids and caustic alkalis produce in time a disintegration of the gelatine, more quickly the greater the strength of the solution. On the other hand, disintegration proceeds very slowly in the cold with alkaline carbonates or ammonia in strong solution.

## BUSINESS METHODS IN THE STUDIO.

### III.

wholesale houses with whom the professional photographer to transact business are generally but few in number, nevertheless what there is to be done should be carried out in a systematic manner. In theory, it is an admirable thing to pay cash for everything, but in practice it will generally be found preferable to obtain credit, the monthly settlements being more convenient than sending remittances every time something is ordered. Now, this credit is not to be gained for the asking.

#### Obtaining Credit.

Sometimes an old-established photographer will send an order to a wholesale house, and will express surprise when a proforma invoice is sent him, together with a letter asking either to send a remittance, or else to furnish references, so that a ledger account may be opened. If he were only to expect that there are many other old-established photographers, any of whom are very bad payers, he would see that the wholesalers, who are quite as anxious to have his orders as he is to have their wares, are only acting in a reasonable manner, and he would always, when doing business for the first time with a firm, give the names of two houses from whom he is already receiving credit, and to whom reference may be made.

#### Starting in Business.

The beginner in business, of course, has no already existing banker's accounts; his plan, then, is to make a confidant of the manager of his bank, telling him his exact position, and then, when ordering, giving the bank as reference. If the professional have not sufficient resources to be able to get a fair report from his banker, he is better out of business. Better for his own sake, and better for that of the profession. There are far too many young men who imagine that the possession of the necessary apparatus is all that is required for starting on their own account. They expect that when a slack time comes, as come it must, they will have nothing on which to live. They cut prices, but go on; the prices that have been cut to meet theirs unfortunately have to remain. A great deal of the bad state of affairs in the profession to-day is attributable to this opening of studios on insufficient capital—a fact which is, seemingly, generally recognised.

#### Ordering Goods.

On return to the matter of buying. The order is made preferably in a manifold book, so as to have the duplicate for reference. It should be clear and concise, and if any other subject has to be dealt with, any complaint or inquiry, should be written on a separate sheet, so that when the order reaches its destination it will be in such a form that it will be sent direct to the despatching department to deal with at once.

#### Invoices and Credit Notes.

Upon receipt of the goods there will be found either an advice (sometimes called a delivery) note or an invoice. The two are compared with the advice note, and this again with the invoice. The latter is checked—the prices with the firm's list or estimate, and the extensions and casting of the totals. If correct, it is filed, a good form of file being that of compartments labelled alphabetically. Should there be an overcharge, the invoice should not be returned, but just corrected, and a letter at once sent to the senders, pointing out the error and asking for credit note. The system of book-

keeping in most wholesale houses is such that when a mistake has been made it has to stand in the books, the credit note, of course, adjusting matters. The credit note is either printed in red ink, or else written in that colour, to distinguish it from the invoice. The receipt of returns of any kind, whether goods or empties, is acknowledged in the same way; the credit note is thus explained in detail, because it is frequently the source of misunderstanding. Invoices and credit notes are filed together until time of payment comes round.

#### Returning Empties.

Most houses charge for cases and allow in full if they are returned in good condition and carriage paid. Some charge at half price, but will not take them back. With goods made abroad, for instance, the hundred-ounce case of pyro the wholesaler frequently sends in "original package," and they are then sent free of charge. Whatever the arrangement, it should be attended to when goods are received, and the case, if of large size, returned at once, or, if small, marked with name of sender, date, and price, and then set aside in a clean, dry place, to be returned when there is a sufficient number to make it worth while. Trade enlargers' packing boards are best returned in bundles. When returning, a list of their numbers and values should be made out, and a postcard stating same sent advising the firm to which they are to be despatched. They should be well tied, and addressed "Returned empties, carriage paid—through to ———." The reason for this is that empties travel at a special low rate, and the latter part is because most of the plate and paper makers and trade enlargers are on the outskirts of London, and unless empties are consigned *through*, cartage or other charges in London have to be paid on account of the railway company receiving them only bringing them to their own terminus. These charges are frequently much more for the few miles than for the couple of hundred miles they may have been sent; whereas, if addressed properly at first, the through rate would be very little, if any, higher than to the terminus. The railway company's receipt for the charges should be preserved, in case empties are lost in transit; it makes claiming more easily done. Should the credit note not be received within, say, a fortnight, and the wholesaler report, upon inquiry, that the empties have not come to hand, the company should be asked to give "proof of delivery." The inquiries they will then make will generally be sufficient to ensure the empties being delivered.

#### Settling Accounts.

The majority of the accounts in the photographic trade are based on monthly settlements being made, so that a statement may be expected during the first few days of the month. This statement will show the balance, if any, of the previous month's account, together with the amounts of all invoices, credit notes, and remittances. A few firms require payment by the middle of the month, others allow until the end, the discount allowed for payment within the time varying. Generally it is 2½ per cent.; the price lists will, of course, give this information. Two and a half per cent. does not sound much, but it is 2½ per cent. per month. Multiply this by twelve, and you have thirty per cent. per annum, which sounds a great deal, and is a great deal, but still (except for compound interest) not more than 2½ per cent. per month. Money is frequently scarce, of course; but many a photographer who could do so makes no effort to effect prompt settlements and secure his discounts—he just sends a cheque for twenty or thirty pounds on account occasionally, not realising that he is foregoing 30 per cent.

or more. Nor must it be thought that the wholesaler is acting otherwise than fairly in this matter of discounts; what he receives in tens of pounds he has to pay out again in hundreds, maybe in thousands—the dealer to the plate and paper maker, and he again to the gelatine manufacturer and the silver refiner.

Prompt payments, whenever possible, should therefore always be made. After verifying the statement with the invoices and credit notes, any discount to which it is subject should be deducted, and then a cheque drawn, payable to the order of the firm, the name being written in full, and crossed

“—— and Co., a/c Payees.” The cheque should be sent together with the statement, and the latter, when returned receipted, should be filed with the invoices, etc., belonging to it, affixed, in the Paid Accounts. These can be kept in similar file to the invoices. By these means the keeping of any Bought Ledger is dispensed with; an invoice, of course, being only to be found in one of two places, simplifying matters at once. The system, to be efficient, though, entails that invoices should be marked when goods are received, and that no statement paid unless such marked invoices can be found for each item.

S. E. KATE.

## WASH-COLOURING OF PHOTOGRAPHS.

[The following article in the “American Amateur Photographer and Camera and Dark Room” provides some hints on a branch of commercial colouring applicable chiefly to landscape work, by whom an enhanced price is often obtained for coloured cards, however bad the colouring may be.—Eds. “B.J.”]

THERE is perhaps nothing that appeals more to the majority of picture lovers than a well-coloured photographic print: on the other hand, there is nothing which so offends one's artistic sense like the many daubs exhibited on every side. And to be able to tint pictures oneself is a pleasure of the picture making process that few realise. There is a certain mysterious fascination that accompanies the wielding of the brush! What colours! what manifold effects are in your power to produce!—but why go on? you will find all this out for yourself, if you only try.

### Transparent Wash-Painting.

Now, it is my purpose in the following article to show how extremely simple the colouring process can be made if a person will only use his eyes, hands, and a sufficient quantity of good judgment and patience. The necessary materials are not many or expensive, the skill required not great, and you will be surprised at the little time and practice that will enable you to produce excellent results. The “transparent wash” is the simplest process known (any one can do it if they exercise the requirements I have heretofore mentioned), and the one most employed for this very reason.

It is for the absolute novice, the “green colourist,” if you will pardon the expression, that this article is intended. Now for a few words in regard to the

### Necessary Materials.

The first thing to procure is the colours. A great number are now upon the market prepared especially for amateur use, and which can be procured at almost any photographic supply house. These colours come in liquid or solid form, but personally I prefer using colours in small pans or tubes to those in liquid, the main advantage being that you cannot spill them. A fancy waistcoat and valuable table scarf, each with a clinging spot of “Sky Blue,” prompt me to offer words of warning against liquid colours. A very satisfactory box of eight colours together with rules concerning mixing to produce other shades and a slip telling about the harmony of colours, can be purchased for the small sum of twenty-five cents. From this price they range upwards to two dollars.

As to brushes, a No. 1 and No. 2 camels' hair will be all that is necessary.

A piece of plate glass (a ferrotype plate will answer the purpose), two or three clean blotters, four ordinary butter saucers for mixing colours in, will complete the equipment.

Having selected a spacious table in some well-lighted portion of the room, place the piece of glass or ferrotype directly in front of you. On one side have your squeegee roller, blotters, and a soft rag, reserving the other side for a glass of plain water, brushes, box of colours and small plates.

### Selection and Preparation of the Print.

While it is true that collodion or gelatine papers, such as Solio and others, may be coloured by first applying a “medium” (usually a liquid to provide a tooth for the colour), still the beginner will find it much more satisfactory to confine his first experiments to papers that will not require any previous “doctoring,” such as any of the brands of developing (gaslight) papers. A grade of these known as “Velvet” is particularly well adapted for colouring. Platinum prints are also easily coloured.

For example, we will say that the print you have selected is a well printed and developed Velox print, untrimmed for the reason that this operation is left until the last, the subject being a landscape with plenty of sky and nice detail in the foreground. Right here let me say that very artistic results can be obtained by colouring photographs that have been printed through silbolting cloth, the effect being a fine mesh-like appearance that resembles paintings on canvas.

The print is now immersed in a basin of cold water (if the water is tepid it is liable to cause the sensitised portion to separate from the paper) for a few moments until it is quite flexible, after which it is carefully picked up by the corners and placed face-up on the glass. Using the blotters and squeegee roller, you can easily remove all superfluous moisture. In this state not only will the print lie perfectly flat, enabling you to work to better advantage, but, furthermore, the wet surface takes the colour more uniformly than a dry one. After this operation, you must turn your attention to what is known as

### The Colour Scheme.

This sounds perplexing to the uninitiated, but in reality it is very simple, if one will exercise good judgment.

Before attempting to mix colours, you must, of course, determine what colours are demanded by the picture before you. A little memorandum as to the colours that you intend using for each object in the picture will prove helpful to the beginner in working.

Let me caution you not to take too much for granted when it comes to the point of deciding what colours you intend using. Many beginners make the mistake of colouring objects in the colour they think they should be without stopping to think whether or not such a condition actually exists. Because you see a lot of trees, hills, and grass, do not think that all of them must necessarily be coloured in brilliant green.

Study nature for your correct colour tones and see how nearly you can reproduce them in your picture. Compare the colour of a certain object, such as a tree, with that of a like object some distance away, and you will be surprised to note how the colour

has been changed by the introduction of that medium artists term "atmosphere."

The first and most important thing that demands your attention in colouring a landscape is the colours you intend using for the sky. The beginner's first impulse is to put down merely the word "blue" opposite to that of sky, upon his memorandum. We observe nature we find the sky to be a series of tints, with the most predominant. Compare the colour of that portion directly above the horizon with the centre of the heavens and note the difference for yourself.

Therefore, for the sky you will need three tints, which, for example, will be pale pink, light blue, and blue. With a few exceptions, this combination is always good. The accompanying diagram will serve to illustrate the comparative area for each colour. Now that you have the colour scheme well in mind (or on paper), the next thing is the

#### Mixing and Applying of Colours.

If the sky is the first portion to be coloured, then you must, of course, prepare its tints—namely, pale pink, light blue, and blue. Colouring the sky first enables you to get these colours more even than if you attempted to put the sky in afterward behind the coloured foliage, etc.

Pour about a teaspoonful of clear water into each of the three dishes, and with your largest brush mix a weak solution of the three colours. A few trials will convince you of the exact length. The light blue is obtained by merely diluting the blue.

Let me caution you again about not mixing the colours too long. Never under any circumstances use the colours in their full strength, as in the end you will have nothing to show for your time but a hopeless splotch.

You are now ready to begin work on the wet print before you. Starting with that portion marked in the illustration CD, and

with your brush well charged with the pink solution, carefully work in the desired space. Let the coloured solution stand for a few seconds, and then blot up the remaining solution. The operation of colouring the entire picture will consist of applying these different washes and successively blotting them.

In like manner as the first, apply the other two colours (their respective areas being BC and AB), blending each colour with the brush slightly dampened with plain water. In working over large areas, such as a sky, for example, your largest brush will prove the most satisfactory.

Once the colours are applied and "set," they will not wash off, and you may have no fear in plunging glass and print into a basin of water and squeegeeing as before in the event the print shows a tendency to dry and curl at the corners.

After colouring the sky, clean dishes must, of course, be prepared before attempting

#### The Foreground and Picture Proper.

Having selected the colours that you are to use for this, you will now proceed in the same manner to make thin washes of each. The broad effect, such as trees and roads, are first worked in with their respective colours. The first wash is for the highlights, and after this a trifle stronger solution of the same colour to be applied to the shadows. It is best to proceed from top to bottom, colouring those things nearest the horizon first.

I might say here that there is nothing that so spoils the artistic excellence of a picture as one colour overlapping another, such as an aureole of green appearing on the sky that surrounds trees, etc.; therefore, be extremely careful in this respect.

Thus having completed the main portion of the picture, the next question is the treatment of

#### Detail.

If your picture calls for "detail," be sure to give it your best time and patience. I cannot emphasise too strongly the necessity of giving attention to those little things in a picture that are at first sight lost if they are not clearly defined.

Even to the colouring of the smartest buttercup by the wayside, to that of a distant house-top, do not become careless, for in the end you will find that it is these little things that show you have been careful, and give your work distinction from the commonplace.

#### Mounting.

After having completed to your own satisfaction the print before you, it may be dried by merely setting the glass in a cool place free from dust.

The print can be trimmed and mounted in the usual way on a good quality of Melton board harmonising in shade to the predominant tones of your picture. If desired, it can then be framed in passe-partout and prove an adornment to any room.

I sincerely hope that the foregoing paragraphs will prove helpful in opening the way to this simple but fascinating branch of picture-making, the charm of which increases as one becomes more deeply absorbed.

JAMES C. SAVERY.

## MODERN OPTICS: THE THEORY OF THE OBJECTIVE PLANE.

Optics is a very progressive science, and the demands of photography have contributed in no small degree to the progress made in recent years. At the same time, there are branches of optics, perhaps it would be better to say, matters concerning optics, that receive very little attention in this country. Germany seems to have taken the lead in the science of optics, and though we need not admit that country to be absolutely first in every respect, we must own that the Germans are far ahead of us in the manner in which they expound optical theories. We need not be ashamed of some of our "all British" optical appliances, such as certain photographic lenses; but there is certainly

nothing to be proud of in our "all British" textbooks, with their antiquated explanations and methods of exposition.

Last year at the Optical Convention much was said about the Gauss theory of "principal planes," and Professor S. P. Thompson asked, "Why is it that we in England have made so little use of the theory of Gauss, which was given to the world something like seventy years ago?" But while it was thus admitted that we are almost hopelessly behindhand in the comprehension of this important theory of lenses, not a word was said at the Convention at any lecture that we attended with regard to the Abbe theory of pupils, which in certain respects

has long supplemented the Gauss theory in modern German textbooks. The Abbe theory is only very slowly creeping into our textbooks in an apologetic kind of fashion, and its importance is hardly likely to be realised until the Gauss theory has been so completely digested as to render its deficiencies apparent. A knowledge of the Abbe theory is essential if the action of a photographic lens is to be completely understood; but this is not the matter we wish to deal with in this article. There is another conception, also due to Abbe, of supreme importance to optical students, but utterly neglected in all English books save one, so far as our knowledge of modern English literature extends—that one exception being the late Mr. T. R. Dallmeyer's "Telephotography."

#### Use of Theory.

The study of the formation of the photographic image, and of the various conditions governing depth and perspective, is a complex matter if we consider the actual paths of the light "rays" through the lens. The Gauss and Abbe theories are both necessary for a full comprehension, but they are not simple theories in themselves, and their application is not simple. Both can, however, be dispensed with if we make use of Abbe's other conception, which we may describe as the "Theory of the Objective Plane." This theory may be briefly described as follows.

#### The Objective Plane.

Under the Abbe theory of pupils the perspective or drawing of the image is governed absolutely and solely by the position of the first Abbe point (or centre of the entrance pupil) with regard to the object. If the image is looked at from the correct viewing point, every part of it is seen under the same angle of view as the object itself when viewed from the first Abbe point. It is, therefore, identical as regards drawing (though not as regards scale) with a perspective delineation of the object made on a picture plane situated in front of the Abbe point and arranged parallel with the plane of the photographic image. This assumed perspective delineation may be considered to correspond to a perspective drawing made according to the rules followed by draughtsmen from the Abbe point as a "station point." If the German expressions used are translated literally we can say that the image on the ground glass, or the "image-side-copy," is an exact reproduction of an assumed "object-side-copy" situated on an imaginary plane in front of the lens. This imaginary plane is the "objective plane," and it is assumed to be the one plane that is in absolute focus. Thus the "objective plane" and the "image plane," or the plane of the focussing screen, are strictly conjugate to one another, and the image on the ground glass is an exact copy on a certain scale of reduction (according to the law of conjugate foci) of the imaginary image on the objective plane.

#### The Consideration of Aperture.

So far we have only considered the matter of perspective, and it has only been necessary to consider the position of the Abbe point or pupil centre. In the more complicated problems, which "aperture" is of importance we must consider the pupil as a whole, and look upon it as a small area from every point which the object is seen. Consider the case of an object point situated either in front of or behind the objective plane, and therefore, "out of focus." If we project an image of this point on to the objective plane, taking the Abbe point alone as centre of projection, a point image is produced; but if we take successively every possible point in the area of the pupil as centre of projection the point will be represented on the objective plane by a disc, or circle of confusion. As every photographer knows, a similar effect is produced in the actual image on the focussing screen of the camera, and, under the theory of the objective plane, each one of the actual confusion discs the image is an exact copy of the imaginary confusion disc on the objective plane, reduced in size on the same scale as that on which the image as a whole is reduced. We thus arrive at the important fact that for any size aperture\* the screen image is an exact copy on a scale of  $N$ -fold reduction of an imaginary image on the objective plane, and as every detail of the imaginary image (for which the term "imago" has been suggested) can be most readily determined by simple geometric perspective rules, nothing beyond a knowledge of the scale of reduction is required to enable us to determine the exact particulars of the actual image formed by the lens on the ground glass screen, the actual course of the light through the lens being disregarded completely. Reference to Dallmeyer's "Telephotography" will show that in this book, which is a worthy monument of its most distinguished author, the matter of depth is considered entirely from the point of view of the objective plane theory. The readiness with which the results are arrived at renders it surprising that other English writers have not appreciated the advantages of the theory, which in the latest German textbooks has practically superseded all the old-fashioned complex methods of discussing depth and other similar problems. In fact, every matter concerning the formation of images, whether photographic, telescopic, microscopic, or visual images are concerned, can be, and is, treated and considered from the light of this theory, which in every case greatly simplifies the expository methods. Unfortunately, English writers up to the present seem to have hardly appreciated the fact that the theory exists, and no one of them seems to have attempted to explain in English its general application, or even to translate any of the numerous German writings on the subject.

C. WELBORNE PIPER.

\* The angular aperture, not the effective aperture, must be considered, if the theory is applied generally to all theoretically possible cases.

## SPOTS IN RAW PAPER.

The following paper on the defects principally met with in raw papers was read before a Continental society of technology, and contains descriptions which should be of assistance to makers of sensitive papers by emulsion or other processes.

EVEN in papers prepared with the greatest care small spots will inevitably appear. Proof of the cause of these spots is of no practical importance as long as they are inconspicuous or occur so seldom that the faulty sheets can be discarded.

Occasionally, however, spots occur in such numbers that they are prejudicial to the use of the paper, and in such cases proof of their cause, which in the majority of cases is a common one, becomes important.

Many of the spots which frequently occur are well known to the paper-maker, so that he can remove them without further

help. The causes and possibilities of the formation of spots are so numerous, and the appearance of the spots is frequently so similar, that it is not possible, without chemical or microscopical tests, to determine their origin. If the constituents of the spots are identified, a conclusion as to the cause of the formation of the spots may be drawn. In many cases, however, accurate knowledge of their structural behaviour and method of formation is necessary, in order to be able to determine at which stage of the work or in which raw material the source of the trouble is to be sought.

Although attention has been directed now and again in the technical press to the appearance of certain spots, the data are so scattered through various journals that it is difficult for the paper-maker to find them.

As far as possible, spots which have been previously described in the press, or communicated by members, and have been met with in my own practice, are now dealt with.

The spots which most frequently occur may be divided into the following three groups:—

A.—Spots, which by reflected light appear darker, but by transmitted light appear lighter, than the surrounding paper.

B.—Spots, which, both by reflected and transmitted light, appear darker than, or of a different colour from, the surrounding paper.

C.—Spots, which are not visible in the raw paper, or at least are not strikingly so, but which appear in the further treatment, such as calendering, painting, parchmentising, or preparing for iron and silver photographic printing.

To Group A. belong resinous, greasy, scum, or sand spots, knots or little balls of conglomerated and strongly compressed fibres and fibrous particles, badly selected paper shavings, etc., masses of silicious or calcareous cells, starch paste.

To Group B. belong iron, bronze, lead, carbon, colour, sealing wax, and rubber spots, coloured fibres, splinters of wood fibre, wood or straw, refuse of hemp and flax, husks of cotton seeds, mouldy growths.

Finally, to Group C. belong fibrous knots, chloride of lime residues, sulphite of lime, starch, iron, resin, grease, sand, rumps of facing, and soft wood spots.

#### Resin Spots.

Group A.—The spots caused by resin can be recognised, as they disappear, or at any rate lose their transparency, by treatment with ether. Frequently, by touching them with a hot needle, one can detect the characteristic smell of heated resin.

After treatment with ether, the spot either completely disappears or there remains behind a depression, a dark place by transmitted and reflected light, or, finally, a white kernel. The dark place contains usually iron, as well as some substances of undetermined constitution, which are soluble in caustic lye with a brown colour. The white kernel consists of matted fibres, which, when treated with the soda lye, swell up, so that they can be separated and examined microscopically, or as gypsum, kaolin, or calcium monosulphite.

The resin spots arise either from the resin of the wood-cell wall, or of the gelatine. The resin spots arising from the wood-cells are frequently larger and more irregularly formed, and soluble with greater difficulty in alcohol and ether than those caused by the gelatine; but exceptions occur, and it is, therefore, seldom possible to differentiate, if no special observations have been made as to whether they arise from the gelatine or from the wood-stuff. Only if calcium sulphite and gypsum can be proved in the spots, ought one to assume that the spots are caused by the resin of the wood-cells.

#### Grease Spots.

The spots arising from grease are very similar to the resin spots, but are generally more sharply defined, and cannot be removed with cold alcohol. If the spot is treated with ether or benzol the grease will dissolve and the spot lose its transparency, but as a rule there remains an opaque spot containing iron or copper. The origin of these spots is, as a rule, to be sought in the bearings and screws of the cylinders. In some cases it has also been observed that they are due to oil slung from the shafts near the paper machine. In the "Wochenblatt für Papier-fabrikation," 1894, p. 1106, a case is mentioned in which, in order to avoid frothing, bearing grease was placed on the cylinders, and this caused green spots.

Froth or scum spots are mostly small depressions in the

paper, sometimes surrounded by a raised ring, which with faced papers is often somewhat more transparent than the middle of the spot, and in a few cases shows another colour than that of the paper. As these spots are a result of frothing, and the latter is caused by the gelatine, the ring, which is formed by the breaking of the bubble of froth, contains some resin. Among scum spots, moreover, a whole series of spots of totally different appearance exist, which also show no special characteristics. Whether the scum was actually the cause in all the observed cases can be seldom definitely determined. But the cause of the froth and the means to avoid it are so well described in the technical press, that it is not necessary to enter into further details here.

#### Sand Spots.

Sand spots are those spots in which grains of sand or micaceous particles, or similar substances are present, as well as those which are really due to sand, which has fallen on the paper during its manufacture or has settled down on the drying cylinders or pressing and calendering rollers. In the latter case the spots formed recur at definite distances in the run of the paper. The spots in which sand is actually found are scarcely noticeable in reflected light, or, when the sand is white or colourless, even by transmitted light. The holes formed by the substances which have fallen out of the same are, on the other hand, distinctly visible, both by reflected and transmitted light. The holes are almost always sharp cornered, and often go right through the paper, as will be seen against the light, just as though a needle had been passed through. For this reason also they are called "pinholes."

The sand which causes these spots comes either from the water, the wood pulp, the stones which grind the latter, or from the facing material. If it is possible to isolate some grains—which can best be done by drawing the paper over a sharp edge—the cause may frequently be determined by the aid of the microscope or chemical reagents. Felspar and mica are, as a rule, from the facing material, quartz from the water or the grinding stone. Absolute certainty can only be secured when one has an opportunity to test the facing material, etc., used. The pinholes are usually formed in the facing of the paper. The grains of sand then, in consequence of the pressure and bending over the rollers, are loosened and fall out of the paper.

Sand spots of a special kind are those appearing in pairs. A contributor to one of the paper journals gives a very satisfactory explanation of the formation of these frequently occurring spots.

If in the paper roll of the calender grains of sand or other similar hard substances are imbedded, if the paper kept its dimensions during the calendering these substances would be impressed twice in the same place in the course of the paper, once in passing the upper, and once in passing the lower steel roller. If, however, the paper expands when passing over the roller, which always is the case, the two imprints will not coincide, but will be shifted a small distance. As the paper alters not only in the direction of its length but also in its breadth, only those imprints which lie in the middle are behind one another, the others show also a sideways shift, which is greater the further they lie from the middle of the direction of the paper.

#### Knots and Balls.

Knots and balls are formed from conglomerated fibres or pieces of badly separated paper wastes. In the unglazed papers they form fine, almost unnoticeable lumps, which only become transparent and noticeable after strong pressure. They are very similar to resinous and grease spots, but differ from these by remaining unaltered when treated with ether, as well as by swelling up in water or lye. If the composition of the stuff of the knots varies from that of the paper it is often possible to draw conclusions as to their origin. Frequently it is essential to differentiate whether the fault is due to a mistake in the

paper factory or whether the raw material is to bear the blame. In deciding between the two, the results of microscopic examination are of great value. If it is determined, for instance, that in a paper prepared from wood pulp, wood fibre, and waste paper, the knots contain, for instance, wood fibre, it is natural to assume that the wood fibre is the culprit; in this special case the badly selected waste paper would be the cause.

The places of origin of the knots may be considered to be the cylinders, the stuff pumps, the knot catcher, and so on.

There is great similarity between the spots caused by knots and those caused by the siliceous cells of straw. In water they swell only slightly; in lye, on the other hand, considerably. They can be easily recognised under the microscope.

#### Starch Spots.

Starch spots are only found isolated, and then only in papers which make no special pretence to purity. They have mostly an angular, somewhat elongated form, which shows that they are due to dried starch. Many spots are incorrectly called starch spots; they contain, indeed, some starch, and generally give a darker blue coloration with iodine solution than the surrounding paper, but the starch is here only as a constituent of the waste paper, the insufficient sorting of which is the true cause of these spots.

#### Metallic Spots.

GROUP B.—The most important and frequent of the spots of this group are those containing iron. They appear in many shapes and from various causes. A conclusion can often be drawn from their shape and nature as to the place of origin of this fault, and therefore this subject is treated fully here. First of all are those which have a kernel of metallic iron. In the freshly made paper they form small black, scarcely noticeable points, which are only unpleasantly visible after dampening, rolling, and storing the paper. The cause is almost always too sharp raising of the cylinders. They may be differentiated from the other ferruginous spots by the fact that the kernel is magnetic, and that it can be withdrawn from the paper by a magnetic steel needle.

The second kind of iron spots contains hard brittle and non-magnetic pieces, which either wholly or in part consist of iron. In the first case they arise from any rusty pipe service, or a rusty water cistern; if they contain also a considerable amount of chalk, they are probably due to the working water containing iron and lime salts. In some cases it should be assumed that they may also be due to detached boiler fur carried over by the steam.

The third kind of iron spot consists of a spongy, ferruginous mass, which, when touched with a preparation needle, falls to pieces, or can be distributed into a paste. In the latter case they contain resin or oil, and sometimes so much that they become transparent, and can then be considered as belonging to the resin or grease spots of Group A. The iron of the powdery spots is most likely due to the water, the iron of the soft spots, on the other hand, to the screws and bearings.

The iron spots described above lie entirely in the fibrous film, and penetrate it more or less.

A fourth kind form the rust spots on the surface of the paper. They are due to porous places in the pressing rollers and drying cylinders. By shifting the scraper of the pressing rollers rust spots and streaks are easily formed. They can be recognised by similar spots, or groups of spots, recurring in the length of the paper at a distance corresponding to the circumference of the cylinder.

Bronze spots, since bronze has been used as the material for the knives of the cylinder and foundations, also belong to the possible faults in the paper. Their appearance when examined microscopically with about a fifty-times magnification, is characteristic: from a dark kernel proceed ramifying rays of a grey-brown colour, which are very similar to fungoid growths, and

have therefore been considered as such by many observers. It is very difficult to find an explanation of the method of formation of these. According to the unanimous opinions many they only appear after calendering. In the kernel of the large spots, which sometimes have a diameter of 4 millimetres (when their starlike form can be easily recognised with the microscope), there will always be found particles of bronze, which, by pressing and rubbing with the preparing needle, show a metallic lustre. In papers with many spots there will frequently be found, on careful search, shining bronze splinters without starlike rays. In most cases they arise from the bronze parts of the cylinders. In some cases they appear, however, on paper in the preparation of which cylinders without any bronze parts are used. As the paper was prepared from sulphite pulp, there is a possibility that the bronze arises from the bronze parts of the boiler attacked by the sulphurous acids.

In wood-pulp, prepared in lead-lined rotary sulphite boiler, small black spots containing lead have been observed in a few cases. Their formation must be ascribed to the unsuitable nature of the lead used.

Coal spots are caused by small splinters of stone or brown coal. They may be recognised by the sharp edges and corners of the splinters, by their inflammability, and by the fact that they are unattacked by acids. Lumps of earthy colours and fillings of material often cause spots. They can be easily rubbed down with powder with the preparing needle. Those caused by the fillings of material are noticeable in coloured papers.

Organic dyes can give rise to faults, either in consequence of incomplete solution, or that they have specially dyed individual fibres, such as wool, cellulose, etc.

By an oversight in the sorting of the lumps, sealing wax or rubber will frequently occur in the paper. The spots consisting of red sealing wax are easy to recognise, but those caused by black wax are difficult to determine, on account of their similarity to other spots. The rubber spots are similar to the resin spots, and are also sometimes somewhat brighter by transmitted light than the paper. Sealing-wax as well as rubber spots are most easily recognised by the characteristic smell which they evolve when touched with a red-hot needle.

Splinters of wood and wood-pulp, parts of the bark, husks of hemp and flax, as well as broken pieces of cotton-seeds cause spots which can be easily recognised under the microscope from the structure of the individual cells. The splinters of wood pulp mostly arise from the wood near the boughs or from the latter themselves; they consist of cells, which vary in form and size from those of other wood cells.

The husks are carried by woody parts of the hemp and flax stalks, and consist of short cells, the appearance of which, apart from their measurements, somewhat recall the cells of bran, wood or straw.

#### Fungoid Growths.

By long storing of pulp in a damp or half-damp condition, fungoid growths appear more or less quickly; they are called foxy stains, which prejudice the appearance and firmness of the paper. In working up the paper, however, they are distributed and decolorised by the bleach that they seldom cause spots. As the fungi, and, as a rule, also their spores, are killed in the drying, they cannot give rise to the formation of fungoid growths in the paper. These may be formed from germs contained in the water used for dampening, or the air, and encouraged by the conditions under which the paper is kept.

As one may conclude from the different coloration of the foxy spots, many different kinds of fungus may appear. Professor Herzberg has described and figured a black fungus which occurs in sulphite pulp. This description also applies to many other fungoid spots. When testing the composition of the spots it should be noted that frequently fungi are found on paper free from spots, which obviously arise from the foxy spots.

of the pulp, and therefore the discovery of a fungoid thread in the neighbourhood of a spot does not lead to the assumption that one has to deal with a fungoid spot.

**GROVE C.**—In the manufacture of paper, defects appear in the product which may be dependent on the raw paper. This kind of fault is undoubtedly the most unpleasant, because the paper maker under certain conditions must be responsible, not only for the paper supplied, but also for the work and materials used in making the paper. As, further, it is not always easy to determine whether the fault is to be laid on the raw paper or on the method of working and materials of the paper user, such cases frequently give rise to widespread legal actions.

#### Defects in Raw Paper.

One of the most frequently occurring questions in the working up of the paper is in the preparation of drawing paper. In his, fibrous knots and splinters of wood, which either project from the paper or swell up through the dampness of the painting material, form small holes in the painted-on film, which, after glazing, give dark shining spots. In testing the cause of such spots special care should be directed as to whether the splinters and knots lie in the paper mass or in the paint from which they are loosely pressed into the paper. In the first case the paper is undoubtedly the culprit; in the latter case, the source of the trouble is doubtful. The splinters and knots can be brushed loose from the raw paper, but they can also arise from the painting material being contaminated with dust. Exact microscopic examination of the knots and splinters, as well as of the paper, can sometimes decide which assumption is correct.

Crater-like depressions in the paint are formed by resin and grease in the raw paper, and give, after glazing, a ring-shaped spot.

Iron is usually only first to be seen when the painted paper is mounted on a card and the starch paste dries slowly, so that the water has time to act on the iron. If the starch paste be dried, the action is naturally hastened. Whether the iron which produced the spot was in the paper or the card must be determined by separate tests, i.e., by treatment with acidulated ferricyanide solution.

If the paper is pasted on to tin plate, and if for any reason the drying of the adhesive material is slow, rusty spots will be caused on the paper. In all cases met with up to the present, the iron in the tin plate is the cause. The damp reaches the sheet iron through very fine holes, not visible to the unaided eye, in the tin coating, and causes the formation of rust and diffusion of the iron into the paper. If a piece of paper free from acid is dampened with distilled water and laid on the metal plate, rust spots, in about two hours, appear, if care is taken

to ensure slow drying. That this disadvantage can be avoided if the evaporation of the water in the adhesive material is hastened, or at least not hindered, was proved by pasting the same paper on a number of flat iron boxes. The paper on the sides was free from spots, that on the flat cover, on the other hand, very rusty, because the boxes, after the pasting, were placed one over the other, so that the damp could only escape very slowly.

Sand and similar substances cause holes or small dark spots in the painted paper. Whether in this case the raw material or the paint is at fault is often very difficult or impossible to determine, especially when some of the unpainted paper cannot be obtained.

In parchmentising, many faults may arise from many causes which can be ascribed to the raw paper. The proof succeeds in this case only if the raw paper can be tested, on account of the strong action of parchmentising mediums.

Resin and grease prevent the action of the acids, chalk and chloride of lime neutralise the acid and give rise to air bubbles, which prevent the penetration of the acids.

In the preparation of papers for tracing or for photographic processes of all kinds, although the paper may be prepared with every care, failures will show themselves, the causes of which probably lie in the paper. These defects are frequently of such a nature that it is not possible to investigate them with the microscope or the usual reagents. In such cases a trial should at least be made as to whether the paper or the method of treatment gives rise to the faults. As the trouble often appears only with a certain treatment and under certain conditions, such as warm air, damp, etc., which are not known or which cannot be maintained exactly, the experimenter is forced to a more or less roundabout method of test.

Tracing paper, which is prepared by saturation with drying oils, etc., acquires, when the raw paper contains iron (sometimes after long storing) brown spots, which do not make the paper useless, but which give it a bad appearance. Here the spot is caused not only by the colour of the iron, but also by the oxidation of the oil produced by the iron. Besides iron, knotty fibres and imperfectly sorted waste paper give rise to spots. The fibrous knots become thicker in glazing than the rest of the paper, and therefore take up less of the preparing medium; the lumps arising from waste-paper retain some of the first sizing, and therefore differ as regards their absorptive capacity for the oil and other liquids from the rest of the paper. In iron printing papers fibres containing lignine cause defects, because they attract and reduce iron, and especially the cyanogen compounds of iron.

G. DALEN.

(To be continued.)

## ENLARGED NEGATIVES ON STRIPPING BROMIDE PAPER.

An article appears in the current issue of our Dresden contemporary, "Die Photographische Industrie," in which are given a number of recommendations as to the making of enlarged negatives on the stripping bromide paper, which seems to be an article of common supply in Germany. Our contemporary dwells upon the advantage to photographers of being able to prepare a number of enlargements quickly and inexpensively, while at the same time being able to produce results which are not of the uniformity inseparable from bromide paper. Its recommendation is to employ a stripping paper which may be exposed in any daylight enlarging apparatus, and has the advantage that it permits of considerable retouching being done before the prints are taken from it. The paper, as our contemporary proceeds to point out in a series of practical hints, must be exposed for somewhat longer than the ordinary bromide paper, and also must be developed to a considerably greater apparent density than is the case with bromide prints. The developed, fixed, and well-washed negative

is then placed film side in contact with a glass plate and squeegeed down. The contact with the glass plate must, of course, be perfect, and the glass must be well-cleaned just as when squeegeeing gelatine prints. When the paper is completely dry the transparent film is easily detached from the paper support.

A very necessary precaution to take is to employ all the baths at a temperature not above 8 to 10 C., using, therefore, for this purpose a developer which works well at these comparatively low temperatures. In this way it is easy to avoid the partial frilling which takes place unless such precautions are taken. In squeegeeing the paper to the glass a roller squeegee should be used and care taken that the film is uniformly brought in contact with the glass, otherwise water and air bubbles will be left. The stripping of the paper should not be attempted until complete dryness has been obtained, otherwise there will be every probability that the gelatine film will tear or rack up. It is best to employ moderate artificial heat until the paper

eventually separates spontaneously from the gelatine film. The paper may be allowed to dry, retouched, and then squeegeed, but it is difficult to judge of the proper strength of the retouching in the case of a rather opaque paper, and therefore it is best to postpone any retouching until the film has been transferred to its glass plate. In all cases plenty of time should be given, at least half an hour, to softening the paper before squeegeeing, otherwise it cannot be expected to adhere.

The finished glass negative shows scarcely any difference from a negative made in the ordinary way direct in the camera, except that there is a peculiar fine grain over the film which facilitates any retouching with a lead pencil. As it is possible to watch the progress of the development only on the surface of the paper, it is scarcely likely that the negative will be too dense. Most likely it will be on the thin side, and so much so as to need intensifying. The mercury intensifier acts very promptly, but on account of the liability of the gelatine to frill at the edges it is far better to obtain a negative of the right strength to start with instead of trusting to after-treatment, and with a little practice the attainment of good density presents no difficulty. The negative image, as transferred to the glass, is laterally reversed as regards right and left compared with an ordinary negative, and therefore gives laterally reversed prints except by single transfer carbon on a similar process. If prints are to be made on ordinary direct papers, it is necessary to place the transparency from which the enlarged negative is made with its film side outwards in the enlarging apparatus. In this way a laterally reversed negative is obtained, from which correct prints can be taken.

In order to give facilities for convenient retouching, the paper may be squeegeed on to an ordinary plate of ground glass, being placed in contact with the smooth surface. On the matt side of the glass a good deal of local control can now be carried out. Any portions required may be lightened or darkened, points of light inserted, etc., all with a pencil or stump.

Altogether, the use of a stripping bromide paper would appear to have many recommendations for amateur use and in enlarging establishments. While permitting of the facilities which plates possess, they are comparatively inexpensive since the glasses which serve to support them can be repeatedly used.

#### ROYAL PHOTOGRAPHIC SOCIETY.

THE following committees have been appointed:—

Fellowship Admissions Committee.—Pictorial Section: Messrs. H. W. Bennett, John A. Hodges, E. T. Holding, Fred. Hollyer, Rev. F. C. Lambert, M.A., Furley Lewis, J. C. S. Mummery, A.R.I.B.A., F. J. Mortimer, and B. Gay Wilkinson. Scientific Section: Messrs. Conrad Beck, Geo. E. Brown, Douglas English, B.A., T. E. Freshwater, F.R.M.S., A. Haddon, Chapman Jones, F.I.C., C. H. Oakden, E. Sanger Shepherd, and Major-General J. Waterhouse.

General Purposes Committee.—Messrs. A. W. W. Bartlett, Leslie E. Clift, T. E. Freshwater, F.R.M.S., E. T. Holding, J. C. S. Mummery, C. Welborne Piper, A.R.I.B.A., H. Snowden Ward, and B. Gay Wilkinson.

Exhibition Organising Committee.—Messrs. A. W. W. Bartlett, Leslie E. Clift, E. T. Holding, C. Welborne Piper, and B. Gay Wilkinson.

Exhibition Selecting and Hanging Committee.—Pictorial Section: Messrs. W. R. Bland, W. T. Greatbatch, Furley Lewis, J. C. S. Mummery, G. A. Storey, and B. Gay Wilkinson.

Journal Committee.—Messrs. Leslie E. Clift, C. E. K. Mees, D.Sc., and Major-General J. Waterhouse.

Journal Advertisements Committee.—Messrs. A. W. W. Bartlett, Leslie E. Clift, and J. Sterry.

Portrait Gallery Committee.—Messrs. E. T. Holding, F. Hollyer, Furley Lewis, and F. J. Mortimer.

Delegates to the Affiliation.—Messrs. H. W. Bennett, Leslie E. Clift, and F. J. Mortimer.

Abstractors and Reviewers.—Abstractors: Messrs. T. Thorne Baker, F.C.S., Geo. E. Brown, F.I.C., A. J. Bell, J. Denny, F.I.C., A. Haddon, H. Holcroft, M.A., F.C.S., C. E. K. Mees, D.Sc., A. J. Newton, H. H. O'Farrell, C. Welborne Piper, E. W. Prevost, Ph.D., F. F. Renwick, S. E. Sheppard, D.Sc., F.C.S., E. J. Wall, and Major-General J. Waterhouse. Reviews: Messrs. S. D. Chalmers, M.A., C. E. K. Mees, D.Sc., A. J. Newton, and S. E. Sheppard, D.Sc.

#### PATENT LAW REFORMS.

UNDER "Ex Cathedra," on another page, we comment on the reforms in patent law which are to be introduced by the present Government. The following abstract of the recent address delivered in the House by Mr. Lloyd-George on introducing his Bill, which quote from the "Chemist and Druggist," will give an idea of the way in which chemical patents in particular will be advantaged.

"Mr. Lloyd-George, President of the Board of Trade, introduced on March 19 a Bill to amend the law relating to patents and designs, and also stated that a Consolidation Bill will shortly be introduced. The Bill, he explained, is to prevent the patent law being used for the hindrance and suppression of British industrial development. At present the patent laws are largely utilised by foreigners to prevent the patent being worked in this country. The new Bill is to put a stop to the vague terms which are used in patent specifications, and held to cover inventions afterwards made. The compulsory-licence clauses introduced in the last Patent Act have been found to be unworkable. It is now proposed to make compulsory licensing effective without cumbrous and expensive litigation. It cost Mr. Levenstein £4,000 to expose the futility of the present machinery. The Patent Office is to have the power of calling for samples in cases of vague and comprehensive claims. Mr. Lloyd-George instanced the case of chemical patents. At present a foreign inventor inserts in his specification every possible combination without ever having tried them. This worked against the British inventor, who afterwards made a discovery which could be some means be covered by one of the suggested combinations. A powerful foreign syndicate has been in operation for some time, and this syndicate would bring an action against the British inventor for infringement of patent. They included possibly as many as fifteen or sixteen counts in their indictment; they employed the ablest and consequently the most expensive counsel at the British Bar, and the best scientific experts. The result was that the poor British inventor, before there was time for his invention to take root or to become a success, was simply overwhelmed by this tremendous combination. In that way many British industries have been wiped out. Another important feature of the Bill is to be the prohibition of restraining clauses on the sale of patented articles. The practice has been held to be legal, and not in restraint of trade. A man selling a bootmaking machine, for instance, will make it a condition that no other machine be used at the factory for 20 years. These conditions will in future be nugatory. The Bill, which was introduced under the ten-minutes' rule, was well received, and loudly cheered as the first reading was announced."

## Photo-Mechanical Notes.

#### Relief Designs by Photography.

In answer to a reader of his photo-engraving columns in the "Ink Printer," Mr. S. H. Horgan gives the following method of producing the effect of relief modelled type from ordinary black and white impressions or drawings.

First have your drawing made, or your type set, in a proper spaced bold-face type. Make a negative of this and then a positive on glass by the wet-plate process. Intensify this positive with copper and silver. Bleach it again with copper and wash well, so that you have white letter on clear glass. Now lay this glass positive, back down, on a light-gray piece of cardboard, and you will find that the letters will throw shadows on the gray background, and by making a half-tone negative from this glass positive the effect will be that of a relief mould design. You will understand that the thickness of the glass on which the positive is made at the angle at which the light falls on it regulate the amount of shadow.

#### Mechanical Inking and Printing of Engraved Plates.

According to the patent (No. 9,311, 1906), of Thomas Macdonald, 6, Barnsbury Terrace, London, N., it has been found possible

printing to perform the inking, scraping, wiping, and cleaning the plates in the following way:—

The main frame carries the various inking jiggers, scrapers, wipers, polishers backwards and forwards across the surface of the engraved plate, while the co-operating organs bring them into action in sequence.

At one end of the machine frame there is an ink duct and inking rollers, with scrapers and the like thereon, while at the other end there is a chalk duct and chalking table, having scrapers, brushes, and the like thereon.

The action of the main frame in passing to one end of the machine carries the inking jiggers and ink scrapers over the inking rollers, to re-ink the jiggers, and the scrapers carry the surplus ink to the plate back to the inking table and deposit it thereon, while wipers and polishers clean the engraved plate.

At the return passage of the main frame to the other end of the machine frame the wipers and polishers are carried over the chalking table, and are scraped and rubbed by brushes, while the inking rollers pass over the engraved plate, inking it, and the surplus ink is taken from the plate by the ink scrapers, which are made of a soft material, so as to reduce the wear or injury to the engraved plate during the scraping.

The inking jiggers and ink scrapers with wipers and polishers are carried with a swinging motion during their passage over the engraved plate, and over the chalking and inking tables. The middle of the machine frame between the chalk duct and the ink duct, there is a hot plate apparatus on which the engraved plates while being inked and cleaned.

During the operation of printing the engraved plate is carried to the inking and cleaning position to the roller and printing rollers on the press, where it receives the paper, packing, and is ready for printing in ordinary sequence.

#### Messrs. Griffin's Catalogues.

Following on the recent official opening of their premises in Kings-Messrs. John J. Griffin and Sons, Limited, send us their catalogues of apparatus and materials for photo-engravers, at the same time reminding us that they have a special demonstration department for this branch of their business, where they will be able to show purchasers every facility for learning the properties of their new introductions. In addition to issuing a list of chemicals and materials for photo-engravers, Messrs. Griffin publish a handsome list of the Kohinor screens with some excellent examples of the work done by them. They also stock "Planoid" copper, a new grade of American copper possessing a minimum liability to scratches and a high perfection as regards flatness. We hope to refer shortly to one or two special lines of interest to photo-engravers which Messrs. Griffin have now ready.

#### PHOTO-MECHANICAL PATENTS.

The following patents have recently been applied for:—

**REPRODUCTION PROCESSES.**—No. 5,375. Improvements in lithographic and letterpress photo-process reproduction. Richard Templeman, William Neil Turner, Robert Turner, and Alexander Wilmour, 15, Water Street, Liverpool.

**PRINTING BLOCKS.**—No. 5,515. Improvements in the production of printing blocks. Sherard Osborn Cowper-Coles, 82, Victoria Street, Westminster, London.

**CELLULOSE MANUFACTURE IN JAPAN.**—The Nippon Cellulose and Artificial Silk Company, Limited, which was registered in London on December 4, 1906, has acquired ground in Japan for its factory. The nominal capital of the company is 4,000,000 yen (£400,000), and it consists of 80,000 ordinary shares of £5 each (one-third paid up), and 2,000 deferred shares of £1 each. The company has adopted an agreement with the Dai Nippon Manufacturers, Limited, and is now busy on the business of manufacturers and dealers in celluloid, paper, natural and artificial fibres of all kinds, silk weavers and dyers, manufacturing chemists, etc. The registered office is at the Chamber House, South Place, Finsbury Pavement, London, E.C. Japanese correspondence informs us that the company intend to produce three tons of celluloid and a ton of artificial silk daily.

## Exhibitions.

### NORTHERN PHOTOGRAPHIC EXHIBITION.

We have once more to place upon record our high appreciation of the methods of attack, the enthusiastic labours, and the completely satisfactory results of Northerners. On March 22 the combination exhibition of workers in Liverpool, Manchester, and Leeds was opened by the Lord Mayor in the stately halls of the Walker Art Gallery, Liverpool, which the municipal authorities have placed at the disposal of the photographic societies of the three centres.

The impression made upon the visitor, especially if he be a Londoner, unused to the frank and breezy cheerfulness of Northern towns, is one of intense life and action, everybody going ahead with a will and doing things with a red-hot enthusiasm. The rooms are hung with perfect taste, and display 670 pictures. Most of these are, of course, not new works; but though they are old, they are old friends. Besides this, there is a special room for lantern slides, the display of which is admirably managed by screened lights, which illumine them in a steady, equal way that we have never seen surpassed.

Amongst such a mass of good work it is almost impossible, and would certainly be misleading, to select any for detailed criticism. Generally speaking, we may state that the work in no case falls below a good average, and it is not too much to say that the show profits by the advantageous fact that it does not deal with entirely new work, as do the two leading London shows. Experiments and impertinences in picture-making by London workers do not come so far as Liverpool. They are sufficiently trounced in London. The Northern shows, therefore, get those works which have survived criticism and discouragement. As a result, there are no "wicked" things, and the average is really higher, artistically and technically, than a London show with its sensations and novelties.

There are, nevertheless, a great number of works exhibited for the first time, and amongst them we should particularly mention Mr. C. F. Inston's views on the Mersey, showing the new dock offices, with fine pictorial effect. "Across the Dock" and "Early Morning in Dock" we hope to see again in London in the autumn. A particularly rich print of eel boats on the Thames shows the mirrored images in the broken surface of the water with splendid effect. This Mr. Inston calls "Reflections." We must not dwell upon his work further, though we have not exhausted his new things.

The work of Mr. C. F. Stuart, which came as a pleasant surprise at the last Royal show, is carried still further at Liverpool. Perhaps the most impressive is "The Grey Mist's Shroud," a large bromide print occupying a commanding position. All his works have great pictorial qualities, and he seems to work the gum process with as much facility as success. If anything, he may be thought by some to have an eye too sedulously on the look-out for the conventional in picture-making. Mr. J. Dudley Johnston competes strongly with him. Mr. Johnston is, perhaps, more original, more prompted from within, than is Mr. Stuart. His "Impressions" of Liverpool and the River Mersey are very distinguished works, showing fine feeling for the beauties of atmospheric effect.

Romantic feeling is highly developed in the work of Mr. Walter Bennington, whose view of Stonehenge, called "The Temple of the Sun," is particularly impressive, and whose "Pines" is at once dignified and eloquent.

There is an excellent series of portraits of members of the Liverpool Society by Mr. John Smith, and amongst them that of Dr. C. Thurstan Holland is most appropriately supported by Miss Brenda Johnson's "Springtime." The point of this arrangement will not escape those who remember the subject of Miss Johnson's picture. Dr. Thurstan Holland himself exhibits a set of prints and slides of Swiss mountain scenery, the former mostly in the oil process. They are forcible and clever.

Herr R. Dührkoop is, we are pleased to note, well represented, especially as the show does not include foreign work to any great extent. His "Mother and Child" is beautiful in its happy catching of a sweet expression in the face of the mother. The child is lively in the extreme. Very decorative and of charming texture is the "Study of a Head," wherein the treatment of the hair, with berries and leaves entwined, adds a classic grace. The portrait of Professor

Arthur Nikisch, also by Dührkoop, is marred by the unsatisfactory and obtrusive posing of the hands; but the head is extremely strong in character—a handsome subject, with fine introspective expression.

Amongst other work which has not been shown in London are Mr. James Shaw's costume pieces, taken under privileged circumstances in Germany during an historic fête. "A Warrior Bold" is a capital study of a man-at-arms, the worse for conviviality, his collar rumpled and twisted awry.

Mr. Furley Lewis shows to advantage a set of portraits in his inimitable style. Amongst them are Prince Peter Kropotkin, Dr. Howard Barrett, and the late H. G. Moon (painter). From personal knowledge we can testify to the excellence of these as likenesses wherein the characteristics of the sitters are not belied. Mr. Furley Lewis is above sacrificing this important consideration to meretricious aims at a startling effect.

We may mention a few works before closing this review which space forbids us to treat of at greater length. "A Northern Waterway," Thos. Carter; "Drear December," A. Dawson Berry; "Evening," E. Warner; "Profile Study" H. J. Mallabar; "Harrington Mann, Esq., and Children," J. Craig Annan; "Nocturne—Gloucester," W. A. Clark; "The Rescue," Ellis Kelsey; "A Green Sea," Joseph Appleby; "Dwellings of the Humble," Rev. H. W. Dick; "Venice in Liverpool," Edwin Kite; "A Vegetable Cart," J. West Lang; "Windswept," Fred Whittaker; and "Patterdale," B. Ward Thompson. These are all remarkable works, and, we believe, have not yet been shown elsewhere.

The slides are, of course, largely repetitions of the subjects of the prints, and many are old friends. But they make an excellent and very extensive show.

The awards, it is pleasant to know, seem to have received hearty endorsement from everybody, and this unusual fact must be very gratifying to the judges, Messrs. J. Craig Annan, Furley Lewis, and W. R. Bland. The award winners are as follows:—

W. A. Clark (No. 188), "Nocturne—Gloucester."  
James Shaw (No. 237), "A Bit of Renaissance."  
E. O. Hoppe (No. 370), "Cecil Heywood, Esq."  
J. Dudley Johnston (No. 423), "An Impression, Liverpool."  
C. J. Whitehead (No. 428), "A Mersey Dock."  
C. F. Stuart (No. 459), "Breezy Upland."  
T. Lee Syms (No. 462), "The bud is fair. Oh, who shall tell if such the rose will be?"  
Miss Hilda Stevenson (No. 469), "Contemplation."  
J. M. Whitehead (No. 478), "The Silent Moor."  
Adelaide Hanscom (No. 554), "Would but some winged angel, ere too late, Arrest the yet unfolded scroll of fate."  
Rudolph Dührkoop (No. 557), "Mother and Child."  
W. A. Clark, No. 9 in lantern slides. Pictorial set of six: 1, "A Norman Vista"; 2, "The Abbot's Chapel"; 3, "Early Morning Sun, Gloucester"; 4, "A Mediaeval Market Place"; 5, "A Corner of the Market Place"; 6, "A Winter's Night."  
John T. Roberts, No. 59 in lantern slides. Technical set of six: "Spiders at Work."  
J. H. Taylor, M.A., No. 69 in lantern slides. Technical set of six scientific subjects.

H. Wormleighton. Two awards for stereoscopic slides.

We must add a word as to the efficiency and beauty of the catalogue. Its illustrations are in the best style, and it appears to be free of misprints—a most unusual thing in catalogues. Its price is 1s., but it is an excellent shillingsworth.

The success and smooth working of this exhibition, which is open for three weeks, and provides lectures upon every evening, is due to the hard and willing work of a band of enthusiasts, among whom should be specially mentioned Messrs. Inston (the indefatigable secretary), and Dr. Thurstan Holland (the efficient and helpful chairman), besides Messrs. John Smith, C. F. Stuart, J. Dudley Johnston, and Dr. Ellis.

#### WEST SURREY PHOTOGRAPHIC SOCIETY.

The nineteenth annual exhibition of the West Surrey Photographic Society was held from March 20 to 23 inclusive at the Railway Hotel, Battersea Rise. The judge, Mr. F. J. Mortimer, made the following awards: Silver plaque for best picture in exhibition, "Morning Calm," V. Nichols.

Class I. (members who have taken awards during the past three years), bronze plaque, "Sunbeams in the Crypt," A. Lockett; bronze plaque, "Daisies," Mrs. W. H. Goy; commended, G. W. Rowse (twice), V. Serin, A. Lockett, W. H. Goy (twice). Class II. (other members), bronze plaque, "The Path Thro' the Woods," G. N. Collins; bronze plaque, "A Moorland Track," G. E. W. Herbert; commended, G. Herbert (twice), R. H. Baskett, F. White, and G. H. C. Matthews. Lantern slides, bronze plaque, "Woodland Path," W. H. Wilshire; commended, F. G. Tryhorn.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents were made between March 11 and March 16:—

**RADIOGRAPHIC PLATES.**—No. 5,784. Improved method of manufacturing radiographic and other photographic plates and papers. Thomas Thorne Baker, and the Gem Dry Plate Company, Ltd., 92A, Villiers Road, Cricklewood, London.

**PHOTOGRAPHY.**—No. 5,786. Photographic improvements. William Francis Robertson, Flower Bank, Gourrock, Scotland.

**COLOR PHOTOGRAPHY.**—No. 6,098. Improvements in the production of photographs in natural colours. Jan Szczepanik, 70, Chancery Lane, London.

**TELECROPHOTOGRAPHY.**—No. 6,334. Improvements relating to the electric transmission of photographs. Ferdinand von Madaler, 7, Southampton Buildings, London.

**APPARATUS.**—No. 6,339. Improvements in photographic apparatus. Ferdinand von Madaler, 7, Southampton Buildings, London.

**DAYLIGHT LOADING.**—No. 6,419. Improvements in daylight loading devices for cameras. James Henry White, 18, Southampton Buildings, London.

#### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**CAMERA ATTACHMENTS.**—No. 16,923. 1906. The inventor states that noticeably tall objects appear taller to the eye than the really are, and the same thing is true of noticeably broad objects. For instance, the letter "T," when its two parts have the same length, the stem or upright portion has the appearance of being longer than the head or cross portion to the majority of eyes. In photographs the ordinary optical impression, as hereinbefore explained, is not produced, as the photograph is mathematical or proportionately true of the object photographed, and by reason of its reduced size, it does not give to the eye the same impression as the original.

It has been proposed to overcome this drawback by the employment of prisms arranged to suitably refract the light which passes through the lens, and it is the object of my present invention to provide a device embodying prisms suitably mounted for easy adaptation to any of the usual forms of camera lens tube and having means for adjustment. The device consists of front and rear prisms, mounted within a lens tube, and having adjusting means consisting of crank arms connected to the pivots of the prisms, there being an adjusting stem engaging the crank arms, so as to rock the prisms simultaneously in opposite directions, in order to bring an image to the relative proportions, as seen by the eye in viewing the original, or to distort an image to the extent of caricature, or to permit of the production of true image, such as obtained with an ordinary camera lens.

The device of the invention includes a tubular case 1, which is open at opposite ends, and is preferably provided at its forward end with an internal annular flange 2, to somewhat reduce the exposure opening 3 at the front of the case. The rear end of the case is provided with a reduced portion 4, which is cylindrical in shape and provided with a lining 5 of felt or other similar material, capable of affording a light-excluding joint when

reduced terminal 4 is placed upon the lens tube 6 of any conventional form of camera, such as is shown at 7 in Figure 1 of the

drawing. Within the case 1 is a pair of transparent prisms, 8 and 9, disposed in opposite relation, that is to say, with the base of one prism extending in the direction of the apex of the other prism, each of which is provided with diametrically opposite trunnions 10, having bearings in opposite sides of the case, whereby the angular disposition of the prism may be adjusted. These prisms are spaced one in front of the other, and when disposed in parallelism, as shown by full lines in Figure 3 of the drawing, the refraction produced by the first prism 8 is corrected by the second prism 9, wherefore the light rays strike the lens in the same relation as when the prisms are not in place. By tilting the prisms to the same extent from their normal relation to the position shown by the dot and dash lines, the refraction of the light rays caused by the prisms will reduce the width of the image and thereby give the same an apparent increase in length. By adjusting the prisms in the opposite direction, to the positions shown by the dotted lines, the refraction will be the reverse, that is to say, the image will be widened, and therefore have the impression of being shortened. By careful adjustment of the prisms, the image upon the ground glass may be brought to a precise reproduction of the impression received by the eye when viewing the original. Furthermore, by materially increasing and decreasing the refraction and only by adjusting the prisms to individually different angles from their normal positions, the image may be distorted to the point of caricature.

In practice the camera is focussed in the usual manner, and then the finger piece 14 is manipulated to adjust the prisms until the image upon the ground glass gives the same impression as that obtained by the eye when viewing the original.

The arrangement shown in figures 3 and 4 permits correspond-

Fig. 3.

Fig. 4.

ing adjustments only of the prisms, and in order that the prisms may be individually adjusted, I employ the means shown in Figures 1 and 2, wherein the trunnions 10 project externally of the case and carry spring arms 18, each of which has its free end bifurcated as at 19, to receive the disc 17 upon the inner end of the threaded adjusting member 12, as hereinbefore described. By reason of the elasticity of the arms 18, they may be independently lifted or spring out of engagement with the adjusting stem and then moved to adjust the corresponding prism individually of the other prism. By preference, each spring arm has a depression 20 to frictionally bear against a flat boss 21 provided upon the exterior of the case, whereby the crank arm and the corresponding prism may be held against accidental movements when adjusted independently of the adjust-

ing stem 12. Willis Eugene Phillips, Collbran, Mesa, Cal., U.S.A.

ENLARGING APPARATUS.—No. 5,179. 1906. The invention consists of an apparatus obviating great extension of bellows. The sliding holder A is a parallel strip of brass, iron, or any other suitable metal or material, and is adapted for sliding, either by a slot, Fig. 2, or by sliding in a groove, or by any other means by which

Fig. 5.

Fig. 1.

Fig. 4.

the distance between H and D can be altered, for the purpose of focussing or for different degrees of enlargement. H being the lens and D the negative, or object being operated on.

The holder A is bent at right angles, at a certain distance from the end, the slot being continued some distance up the vertical portion, to enable the object copied to be raised or lowered, so that different portions of the same can be placed central with the lens, the object to be fastened to the holder A by a small clip B, with a screw or any other suitable fastening, and the clip being able to slide up and down the vertical arm of A.

The holder A to be fastened either to the baseboard of camera

Fig. 2.

G, or to a board or table to which the camera is fastened, by a screw or other suitable fastening. F is the camera front. The claims are:

(1) "A supplementary fitting for a camera for the purposes described, consisting of a slotted extension piece fitting on to the baseboard of the camera, and carrying an adjustable holder or the like."

(2) "In combination with apparatus claimed in Claim 1, the auxiliary lens fitting for altering the focus of the lens according to requirements." George Smorthwaite, 2, North Croft Villas, Englefield Green, Surrey.

## New Trade Names.

TWINK.—Photographic Dry Plates and all other photographic goods included in Class I. Ilford, Ltd., Britannia Works, Roden Street, Ilford, London, E. Manufacturers of photographic plates, papers and films. February 6, 1907.—Design of a five-pointed stars composed of triangles. Photographic apparatus in Class 8. Fabrik Photographischer Apparate auf Aktien vormals R. Huettig and Sohn, 76, Schandauerstrasse, Dresden, Germany. September 12, 1906.

THE KING AND PHOTOGRAPHERS.—King Edward has been much annoyed for the past two days at Biarritz by the unpleasant pertinacity of the photographers who spring out from behind doors or rocks as his Majesty is passing. The other morning, as the King walked along the sea-front, no fewer than five cameras were levelled at him.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Hand-Camera and Rising Front.

There is often some difficulty (says the "Photographic News," in its highly attractive "Spring" number) in deciding what difference there will be between the view on the plate and that seen on the finder when the front is raised, but the matter is quite simple if the finder is actually or mentally divided into four: the maximum rise of front usually being a quarter of the plate in either direction. If the front is raised to its fullest extent and the camera is held level, one quarter may be reckoned as coming off the bottom of the finder picture and the like space will be added on to the top. With the universal type of instrument, however, there never need be any uncertainty, for the changing box may be removed, the door of the focussing chamber opened at the back, and the image actually focussed on the ground glass, holding the camera opposite the eye. This is obviously unnecessary for ordinary snapshot exposures, but where the utmost certainty is desired it may be secured in this way.

### Patterned Bromide Prints.

An ingenious method (writes Mr. Arthur Payne in "Photography") of hiding all traces of handwork upon the surface of the print, and at the same time conferring a novel texture to the paper, came under my notice some time ago, but I have not yet seen a description as to how it was produced. . . . All that is necessary to produce this effect is to place a sheet of rough glass paper, or a piece of wire gauze, in contact with the face of the finished and mounted print, and then to pass them through a rolling press, or between the rollers of a domestic mangle. This produces a pattern upon the face of the print, and a variety of patterns may be obtained according to the requirements of the moment by selecting suitable embossing material. Personally, I prefer the irregular grain produced by the action of glass paper. The kind of glass paper which I use is that known as Oakey's No. 3, and in order to prevent the grains of glass with which the paper is coated from sticking to the print, it is necessary to see that this is quite dry before it is passed through the press. It will be found necessary to pass the glass paper and print through the press many times before an evenly embossed effect is produced upon the print, and any pieces of glass which may adhere to the surface of the print are removed by brushing them off with a duster. It may be advisable to mention that the glass paper and print must not be repeatedly passed through the press without altering the relative positions of the two between each application of pressure, otherwise a few deep markings will be produced, and not an even roughened surface such as is required.

## New Books.

**AEROGRAPH WORK.**—Those who studied the recent article on working-up and colouring with the aerograph which appeared in our columns during January and February of the present year, will be glad to know that they are now obtainable in booklet form from the Aerograph Company, Limited, 43, Holborn Viaduct, price sixpence. We are gratified to observe the Company adopting the communications to our columns as the official instruction in the use of their well-known apparatus.

**EMPLOYERS' LIABILITY.**—Messrs. W. Speaight and Sons, 98, Fetter Lane, London, E.C., have issued a popular account of the new Act, under the title: "A Simple Explanation of the Workmen's Compensation Act, 1906." The volume costs only one penny, and is drawn up in the interests of both employers and employed.

### CATALOGUES AND TRADE NOTICES.

The current issue of the "Camera House Journal," Messrs. W. Butcher's trade publication, reaches our table containing full notices of the firm's forthcoming novelties, among which is a new 3s. camera, to be called the "Twink."

## New Materials.

"Satin Photo" Mountant. Made by Mendine, Ltd., Tooley Street, London, S.E.

Many as have been the preparations offered to photographers for the mounting of prints, there is, nevertheless, good reason for drawing attention to a new preparation introduced to us as Cole's "Satin Photo" mountant, and placed on the market by Messrs. Mendine, Ltd. This adhesive is evidently different in composition from the majority of such mixtures, and we have never examined a mountant which spread so easily under the brush or gave so perfectly uniform a coating. Added to this, the new mountant possesses a very small penetrative power for paper, and hence it causes little or no cockling even of a thin mount, a quality which confirms the makers in their recommendation of it for the now increasingly popular multiple mounting on an art paper. The mixture is also strongly adhesive, and, so far as we can discover, without any tendency to harm the prints mounted with it.

**P.O.P. POSTCARDS.**—We have received some specimens of postcards made by their Kentmere P.O.P. from the Commercial Photo. Co., Ltd., Kentmere Mills, Staveley, Westmorland. The cards show a fine scale of contrasts, and with very fine whites, and the tone, a rich reddish brown, is of a kind very suitable for wholesale postcard work. The Commercial Photo. Co.'s list prices the cards at 20s. per 1,000, carriage paid.

**POSTCARD MOUNTS.**—Messrs. W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C., send us a number of specimens of the "Nature" postcard mounts of various designs. The attachment of a thin photograph being now permitted by the postal authorities, the postcard mount should gain a vogue which has hitherto been denied to it, and as the photograph may now be sent in this form through the post for one half-penny, a large demand is assured. Messrs. Butcher are preparing twelve varieties, each having an embossed design, for circular, oval, or oblong prints, whilst others will take the full-size quarter-plate print. The prices are sixpence per packet of fifteen, or one shilling per packet of thirty-six; or they may also be purchased in bulk at 2s. 6d. per hundred, or 22s. 6d. per thousand.

**MATTOS PRINTS AT THE MODERN GALLERY.**—An exhibition of the results obtainable on the series of sensitive surfaces, such as silk, satin, linen, wood, and Japanese vellum, prepared by the Mattos Company, was held at the Modern Gallery, 61, New Bond Street, W., on March 25, when a number of prints from negatives of these materials were shown, together with many examples of the Mattos printing-out paper. A demonstration was given of the facility with which the Mattos materials are toned, and considerable interest was shown in the variety of the results obtainable without varying the manipulation. The exhibition, which is worth seeing, closes Thursday, March 28, at 5 o'clock.

Mr. J. M. DICKINSON, of Marion and Co., writes: "Will you allow me, through the 'Journal,' let my friends on my ground know change of my address, which is from this date 95, Fox Lane, Palmer's Green, London, N.?"

**ACKNOWLEDGMENT.**—A correspondent who recently addressed query to us writes as follows: "I have to thank you very much for kind answer to my query re yacht photography, also for giving me address to Captain Owen, of Stourbridge. He has written me several times, and has sent a large number of excellent prints. Indeed, his kindness has been so great that I feel quite uncomfortably indebted to him, with no prospect of being able to do anything in return. I must also thank 'Bhan-O' for his hints, and think, with ordinary good luck, I ought now to get something pretty decent when the next chance comes. It seems strange that the only question I have addressed to the 'B.J.' (though I have taken it for years) should have called forth such kindly feelings."

**WIMBLEDON CAMERA CLUB.**—Mr. J. Munro having resigned the hon. secretaryship of the Wimbledon and District Camera Club, Mr. H. Bridgen, 12, Montague Road, Wimbledon, who has hitherto acted as joint hon. secretary, is henceforth undertaking the whole of the duties connected with that office.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### FRIDAY, MARCH 29.

Lydney Art Club. "Lancashire and Cheshire Portfolio."  
Lydney Photographic Club. "The Choice of a Printing Process." By Hector  
Maclean.  
Lydney Camera Club. Excursion—The Medway from Yalding to Maidstone.

#### MONDAY, APRIL 1.

Lydney Camera Club. Lecture, to be arranged.  
Lydney Camera Club. "Further Hints in Platinotype Printing." J. Barr.

#### TUESDAY, APRIL 2.

Lydney Camera Club. "The Autotype Carbon Process." Demonstrated. By  
Mr. R. Long and Members.  
Lydney Photographic Society. Lantern Slide Competition.  
Lydney and District Camera Club. Annual Meeting.

#### WEDNESDAY, APRIL 3.

Lydney Photographic Society. "Ozobrome." W. L. F. Wastell, F.R.P.S.  
Lydney London Photographic Society. Annual General Meeting.  
Lydney Camera Club. Smoking Concert.  
Lydney Polytechnic Photographic Society. "Ozobrome." By Thos. Manly.  
Lydney Leicester and Leicestershire Photographic Society. "Carbon Printing." Demon-  
strated. W. T. Mason.  
Lydney Camera Club. "Platinochrome." Demonstrated. By W. A. Mackie.  
Lydney Photographic Society. "Ozobrome." Demonstrated. By Mr. Manly.  
Lydney Edinburgh Photographic Society. "The Intensification and Reduction of Gelatine  
Negatives." Illustrated. By A. J. Garwood.

#### THURSDAY, APRIL 4.

Lydney Liverpool Amateur Photographic Association. Meeting and Lecture at Walker  
Art Gallery.  
Lydney North London Photographic Society. Lectures by Members.  
Lydney Cambridge Wells Amateur Photographic Association. "Some Pictures from the  
Valais." By Dr. Starling.  
Lydney Richmond Camera Club. Members' Slides.  
Lydney Photographic Society. Annual General Meeting.  
Lydney Newbury Photographic Society. "The 'Watalu' Self-Developing Plate." By  
C. P. Proctor.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, March 26, 1907. Mr. T. Thorne Baker read  
paper on the "Colour Sensitising of Gelatine and Collodion Emul-  
sions and the Relation of the Colour of the Dye to its Sensitising  
Action." The author referred to the observation that the red  
sensitiveness of a gelatine emulsion becomes greater with its speed  
relatively to the blue-violet and attains sensitiveness to the infra-red  
with slight fogging and bathing with ammonia. On these and other  
points he based a theory of "sensitiveness enhancement," regarding the  
action of dyes as augmenting the latent colour sensitiveness already  
existing in emulsions. After discussing the function of fluorescence  
affecting the sensitising action of a dye, Mr. Baker suggested  
the use of silver nitrate and ammonia in conjunction with many  
dyes which give slight sensitiveness in the ordinary way. Thus  
azo Black B. H. N., in conjunction with silver nitrate and  
ammonia, gave very marked red sensitiveness, almost as great as  
that given by pinacyanol, and better than that given by the latter  
as regards green-sensitiveness. A similar action was observed in  
the case of direct deep black R.W. (Bayer). Diazo Black used in  
this way was suggested by the author as likely to be of service for  
spectrography and three-colour work, as it was infinitely cheaper  
than pinacyanol. Two other dyes which in like manner were found  
to work well in conjunction with ammonia and silver nitrate were  
azo Blue and Benzo Green. Benzo Green acted most notably  
in collodion emulsion. A washed collodion emulsion plate, after  
bathing with solution containing Benzo Green ammonia, silver  
nitrate, and a large proportion of alcohol for thirty seconds, was  
found to have red- and infra-red-sensitiveness up to 9,000 Å. U.  
Accordingly, the author stated his experience that the use of a dye in  
increasing concentration, saying that the infra-red-sensitiveness fell  
as the amount of dye was increased.

In summer Benzo Green was found to give rise to fog, which was  
not where the glass plate came in contact with the pneumatic  
roller. Perfect freedom from fog resulted from keeping the laboratory  
temperature below 40°F. As regards the action of the silver nitrate, the  
author offered the explanation that the insensitive silver salt of the  
dye when dissolved in dilute ammonia become dissociated, resulting  
in the formation of a small quantity of highly sensitive silver bro-  
mide in the film. Mr. Baker gave a number of general conclusions,  
among which was the statement that any aniline or other dye what-

ever is capable of enhancing the sensitiveness of silver bromide to  
some part of the spectrum. Blue iodide of starch was mentioned as  
giving an effect which could be measured.

The method followed by the author in measuring the general  
sensitiveness of a dyed plate and in finding the extreme limit of  
action useful in spectrography, was as follows: A prism camera was  
used, in which extremely weak sensitiveness could be determined.  
A camera was also attached to a spectrometer giving portions of  
the spectrum equivalent to 2,500 units. The dark slide containing  
the plate was first placed centrally and an exposure made. It was  
then displaced slightly, and a line-spectrum photographed, over-  
lapping the first one by about one-third, any position being thus  
determined by means of these lines, in reference to a scale in which  
wave-lengths were plotted against position in the negative. The  
remaining portion of the plate was employed to show any reduction  
caused by scattered light, and also any fog, these quantities being  
subtracted from the spectrometer readings of the spectrum densities.  
The author used a twelve-inch coil with the carbon terminals,  
moistened with a solution containing thallium, sodium, potassium,  
lithium chlorides, and at times used a hydrogen tube to get the C. F.  
γ δ lines. For illumination he employed the limelight for the  
diffraction, spectrum, and arc for the prismatic.

In examining the effects of a dye apart from the behaviour of a  
given plate, the author coated two pieces of plate with an equal  
quantity of emulsion, bathed one after drying with a dye solution,  
and again dried. An H. and D. strip was then cut from each, and  
exposures made for speed, and also in the spectrograph, the illuminant  
for the latter instrument being the same as for the speed tests.  
The exposures in the spectrograph were made in an inverse propor-  
tion to the ascertained speeds, and the plates were developed for  
times inversely proportional to their development factors. On read-  
ing off the densities, those of the unbathed plate were subtracted  
from those of the bathed and the differences plotted against wave-  
lengths. The resultant curve, which the author called the "curve  
of enhancement of colour-sensitiveness," gives the effect of the  
spectrum exposure of the bathed plate minus that of the spectrum  
exposure of the unbathed—in other words, the difference in sensitive-  
ness produced by the dye.

**SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.**—A critical point has  
been reached in the evolution of this new comer. At a meeting  
of the organising committee, at the society's headquarters, 75, High  
Street, Lewisham, on March 20, with Mr. A. Haddon in the chair,  
the hon. secretary's estimate of capital and current expenditure for  
the first year was considered. Mr. T. K. Grant demurred to the  
idea of furnishing or providing apparatus on the basis suggested,  
ridiculed the estimated cost of particular items as extravagant, and  
offered himself to provide a half-plate enlarging lantern and bench  
complete for £5. Ultimately the committee cut down the estimated  
capital outlay to less than half, and current expenditure to about  
four-fifths of the secretary's estimate. The hon. secretary's scheme  
for providing the necessary capital to start the society fully equipped  
at the outset was then discussed and rejected, an amendment being  
adopted, on the motion of Mr. T. K. Grant, postponing consideration  
of ways and means until the general meeting. The hon. secretary  
(Mr. Noon) at once resigned his office, stating that he declined to be  
responsible for carrying out a policy which failed to provide  
for the liabilities which must be incurred, or for the proper equip-  
ment of the society at the outset. Pending the appointment of his  
successor, communications for the society should be addressed to the  
joint hon. sec., Mr. E. W. Andrews, 12, Old Dover Road, Blackheath.

**CROYDON CAMERA CLUB.**—Mr. H. P. C. Harpur last week gave  
a lecture on "Transparencies for Enlarged Negatives," with particu-  
lar reference to a highly ingenious appliance of his own design.  
for making trial and other exposures for dry-plate positives. This  
apparatus, which hardly lends itself to detailed description without  
drawings, can be set to give from six to any lesser number of ex-  
posures: step by step, either across the plate, or what is better, along  
the diagonal. When the correct exposure is ascertained a simple  
shift of a lever allows this to be given. The lecturer strongly pre-  
ferred a good slow dry-plate to a carbon transparency, employed  
Rodinal, 1 in 10, for a fixed time of development, and used a pendulum  
rockers, which he said was undoubtedly better than rocking oneself,

an obviously unanswerable proposition, as stated. It was, however, pointed out by others that the use of a mechanical rocker might cause uneven development if its period of oscillation should happen to synchronise with the flow of the developer, a stationary wave being then set up. This would result in the ends of the plate being more developed than the middle portion. A hearty vote of thanks was deservedly accorded Mr. Harpur.

During the evening several large albums containing a collection of works by members of the Southampton Camera Club, and kindly lent by it, were inspected with much interest. It was unanimously agreed that a very high level of merit was maintained throughout.

## Commercial & Legal Intelligence.

**IMPROPER POSTCARDS.**—At the Bow Street Police-court, Albert Stoop, a Belgian, was charged before Sir Albert De Rutzen with selling improper prints. Mr. Wilson, for prisoner, stated that he (prisoner) would plead guilty. A remand was ordered.

**A LONDON BANKRUPTCY.**—At the London Bankruptcy Court, on Friday last, before Mr. Registrar Brougham, an application was made for the discharge of John Edward Reeves, photographer, of Barking, Essex. The Official Receiver reported that the receiving order was made on November 28, 1906, on the petition of a creditor, and at the first meeting of creditors the Official Receiver was appointed trustee of the estate. The statement of affairs filed by the debtor disclosed unsecured liabilities amounting to £197, but the proofs actually lodged amounted to £208. The assets, so far as they were not assigned to creditors either wholly or partly secured, were estimated to produce £54 3s. 10d., but they had actually realised only £19 3s. 4d., and the probable value of the assets not yet realised was £20, making £39 3s. 4d. in all. The difference between the actual value of the assets and the bankrupt's estimate was accounted for mainly by the over-valuation of his assets. The dividend payable to the creditors was not expected to exceed 1s. in the £. The bankrupt stated that in 1892 he commenced business as a photographer at 50, Hermit Road, Canning Town, with a capital of £5. In 1902 he was suffering from nervous breakdown, and, acting under medical advice, he went to Lowestoft for a year and seven months. The business, which was then solvent, was handed over to his son-in-law, Mr. Hills, who sent bankrupt £2 per week. When debtor returned from Lowestoft he found that Hills had incurred liabilities to the extent of £200, and that the business had been conducted at a loss. The debtor then resumed the management of the business, and he also opened a new business at a cost of £150 at East Street, Barking, which he entrusted to Hill's management. In March, 1905, he conveyed that business entirely to Hills, but the effects were only worth about £5. Debtor continued the business in Hermit Road alone at a loss. In May, 1906, he obtained a mortgage of £225 on the business, out of which he paid certain creditors chiefly connected with the Barking business. Afterwards creditors took proceedings against him. He alleged his failure to have been caused through liabilities incurred by Hill during his absence at Lowestoft. The Official Receiver reported that the bankrupt's assets were not of a value equal to 10s. in the £ on the amount of his unsecured liabilities; that the bankrupt had had little or no education, and had consequently never kept any books of account, therefore the Official Receiver reported that the debtor had omitted to keep such books of account as were usual and proper in the business carried on by him, and as would sufficiently disclose his business transactions and financial position within the three years immediately preceding the date of his bankruptcy. The debtor admitted that he became aware of his insolvency in July, 1904, when he returned from Lowestoft. Since that date he appeared to have contracted new debts amounting to about £35, in addition to the accounts that had been running since 1902; therefore the Official Receiver further alleged that the bankrupt had continued to trade after knowing himself to be insolvent. Eventually the Court suspended the debtor's discharge for two years.

## Correspondence.

- Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- We do not undertake responsibility for the opinions expressed by our correspondents.

### THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION To the Editors.

Gentlemen,—In reference to your comment in "Ex Cathedra" to the lack of *esprit de corps* amongst photographers towards the P.P.A., may I, through the medium of your journal, give my remarks (together with that of several others of the profession with whom I have spoken on the subject) why we have so far given the Association a wide berth.

We have seen scores of photographs—or, I should say, things that were supposed to be photographs, evidently issued by "backyard photographers," or their equals—on mounts adorned with the title M.P.P.A.

After due consideration we have decided not to associate ourselves with this class of photographer, and have therefore held back from purchasing the title for a 5s. fee.

We suggest that if the Association would welcome all classes of the profession to their ranks a few more members could be obtained by the prohibition of the use of the letters M.P.P.A., or at least allow their use to such members only who have proved themselves worthy by passing a professional examination.—One who would see the profession raised, and not lowered, by the use of the title

M.P.P.A.

[We are glad to hear our correspondents' protest, because we are equally against the use of the letters "M.P.P.A." by a photographer. Yet we cannot see how our correspondent can hold the Association responsible for the action of individual members, or how he can imagine the Association to include a majority of what he calls "backyard photographers." As we see it, our correspondents' aims are those of the leaders in the Association, and they would be more likely to be realised when the Association has our correspondents on its membership roll.—Eds. "B.J."]

### SULPHIDE TONING.

To the Editors.

Gentlemen,—In this week's issue of your journal I see an inquiry for a formula for sulphide toning in three solutions, and from your correspondent says he must refer to the iodide bleacher. The best formula I know is as follows:—

Potassium iodide .....	54 grs.
Water .....	4 ozs.
When dissolved, add:	
Iodine .....	22 grs.

This bleaching solution turns the paper deep blue, due to the formation of iodide of starch, and makes the "positive into a negative," as your inquirer puts it, and necessitates the use of a clearing bath, sodium sulphite, 60 grs.; water, 10 ozs.; to which add sulphuric acid, 15 minims.

The prints should be left in the iodine solution for ten minutes, transferred without washing, to the clearing bath, and kept moving until every trace of colour has gone from both sides of the paper. It is then washed and toned in a solution of sodium sulphite, 15 grs. water, 5 ozs.; hydrochloric acid, 5 drops.

The acid improves the colour of the prints immensely. This is the formula I employ for "Special Portrait Velox," mentioned in my letter a week or two ago. It is quite suitable for fine paper.—Yours faithfully,

S. HALL DOWNING

292, South Road, Sheffield.

March 22, 1907.

### STEREOSCOPIC PROJECTION.

To the Editors.

Gentlemen,—The problem of stereoscopic projection has given rise to several processes, which require more or less complicated instruments.

I found lately, in the "Merveilles de la Photographie," Tissandier, the mention of the Claudet's Monostéréoscope, which was sold at Paris in 1858.

The description of the apparatus being not complete, I made

quiry, and found in the "Monographie du Stéréoscope," by De la anchère, the full description and theory of the Monostéréoscope. ere is also a book by Claudet himself, "Le Stéréoscope," but I have found it.

The apparatus is a box with two lenses (placed side by side at ordinary stereoscopic distance), which are fitted so as to allow the superposition of the two images on the same focussing glass. A stereoscopic transparent slide being placed before them at the required distance, and the instrument being turned towards the light, a double image on the ground glass is not, as one could suppose, confused one, but each eye takes naturally the image which responds to it, and the result is a bright and sharp view in bold relief on the glass.

The theory of this phenomenon is fully explained in the book. If such an instrument gives really this result it would be easy to try the same process for projecting stereoscopic slides on a screen in a similar arrangement, by means of a lantern provided with two lights and two lenses, fitted as described above.

Would not a lanternist-reader of "The British Journal of Photography" try this interesting and easy experiment? I should be pleased to see the question examined by your readers.—I am, gentlemen, yours truly,

G. DE BRANDNER.

3, Rue du Chatelain, Bruxelles.

March 22, 1907.

## Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 7s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

Waddington, 420, Bolton Villas, Bradford, Yorkshire. Photograph of reputed Oil Painting by Murillo, entitled, "The Andalusian Flower Girl."  
Hunford, 22, Victoria Road, New Brighton. Three Photographs of the West of the New Brighton Landing Stage.  
Sayers, 25, King Street, Great Yarmouth, Norfolk. Photograph of the Caistor-on-Sea Lifeboatmen.  
Law, 32, Briardale Road, Seacombe, Cheshire. Two Photographs entitled: Landing Stage Smash, New Brighton.  
Winter, 26, Castle Street, Shrewsbury. Two Photographs of Henry John Hoarne.  
Oline, 19, The Avenue, Clifton, Bristol. Eight Photographs: Interiors at Langton Mansion, Bristol.

In consequence of our going to press earlier in order to Publish on Thursday a number of Queries and Answers and other paragraphs are held over.

URING PLATINOTYPES.—I have been tinting on albumen paper and find a great difficulty in obtaining the same effect in platinotype. Is any preparation necessary, and if so, what? And does the same apply to matt. coll. or bromide?—SILVER.

Most colourists, when they wish to produce the highest class work, prefer platinotypes to prints on albumen paper, as they find that upon them they can produce better and more artistic effects. If, however, you prefer a highly glazed surface to work upon we would suggest that you size the platinotypes with gelatine—say one ounce of Nelson's No. 1. gelatine dissolved in from twenty to twenty-five ounces of water, according to the gloss desired, with sufficient chrome alum, or formaline, to render the coating insoluble when dry. If the former be used, thirty grains of chrome alum dissolved in two ounces of hot water will be

sufficient. The solution should be applied warm with a broad camel-hair brush. The same solution will do for the other papers named.

SATURATED SOLUTIONS.—I enclose you a formula, cut from your "Annual," page 967. I cannot understand what is meant by "Saturate with iodide of silver and filter as above." Is there any book published on making lantern slides by the wet process?—IODIDE.

A saturated solution is one which has dissolved as much of the salt as it can at normal temperature. Read "Wet Collodion Photography," by Charles W. Gamble. Price 1s. net, from any dealer.

GLAZING PRINTS.—I am sending you two cards, one glossy, one plain. As I understand, the gloss is obtained by varnishing and drying on plate glass as photos. Can you give me the instructions and advice as to where to get the special varnish? I should esteem it a favour if you would advise me in any way. Trusting you will be able to help me in the matter, and thanking you in anticipation,—H. SINGLETON.

The print sent is apparently glazed with gelatine, and been squeezed on to a glass or ferrotype plate as is usual with P.O.P. prints. You may produce similar results as follows:—Float the prints on a warm solution of colourless gelatine—1 oz. to a pint of water. Let the print rest till the gelatine has very thoroughly set, then squeegee on to a glass plate which has previously been rubbed over with French chalk, or waxed, to facilitate the stripping when dry.

TINTING PHOTOGRAPHS.—I shall esteem it a favour if you will kindly answer the following inquiry in the "B. J." :—1. I purchased some best aniline dyes to tint P.O.P. prints. I made a saturated solution of each colour, and, of course, diluted them before use. The prints are beautiful whilst in a damp condition, but as they dry, the colours, especially the green and yellow, fade. They appear to sink into the gelatine and paper, sometimes showing through the back. Have I omitted to mix something with the dyes? 2. Also please state the proper method of mounting on to celluloid.—IOAN.

1. It seems to us that you have employed unsuitable dyes for the work. Colours specially prepared for the purpose are now sold by all the large dealers, and you would have no such trouble with them. They are very cheap. 2. The prints are first soaked in methylated spirit, and are then laid on a metal plate, the celluloid placed on, and a hot, heavy iron roller passed over the whole, which causes the print and celluloid to adhere. Suitable rollers, etc., for the purpose are specialties of Messrs. Fallowfield, Charing Cross Road.

WATKINS FACTOR.—Could you give me the Watkins factor for the universal developer recommended in "B.J.," January 5, 1906, by Mr. Shenton?—H. MARTIN.

We are unable to say. Perhaps Mr. Shenton, or someone who has used the developer, can give our inquirer the information. But we imagine the factor will not differ from that of a developer with the same proportions of metol and hydroquinone, particulars of which are given by Mr. Watkins in his "Watkins Manual."

SENSITISED VELLUM.—1. Can you inform me what German firm supply Japanese paper coated with P.O.P. or albumen emulsion, and if it is obtainable in this country? 2. What wholesale firm supplies Passe-partout binding strips in rolls for use?—S. E.

1. From Mattos, Ltd., Arundel Square, Highbury, London, N. 2. Cooper, Dennison, and Walkden, Ltd., 7-9, St. Bride Street, E.C.

W. D.—The address is: G. H. Eustace, 306, Cleethorpe Road, Grimsby.

C. H. LITTLE (San José, California).—There are two fairly good books: "A Treatise on Photogravure," by Herbert Denison, and "Photo-Aquatint and Photogravure," by T. Huson. The prices here are 4s. 6d. and 2s. respectively. Probably Messrs. Tennant and Ward, 387, Fourth Avenue, New York, can supply both.

ARCHITECTURE AND MORALITY.—A gentleman calls on me and orders four 12 x 10 photographs of certain villas, but I must not let the tenants know anything of it, as the pictures are only for his personal use, which might not be appreciated by the tenants. I believe it is the designs of architecture he requires. Am I

running any risks by supplying him? First, from a legal standpoint; second, morally. I might mention the said gentleman (tradesman) lives twenty miles away.—VILLAS.

You run no legal risks, as anyone is at liberty to photograph from a public highway any "work of nature," into which category buildings are, in this country at any rate, held to fall. As to the moral question, we cannot say, but we should not consider the taking of photographs for an architect's guidance immoral.

**POSTCARDS.**—Will you please advise me through the medium of your journal on the following point?—I cannot keep my glossy P.O.P. postcards flat, although I notice the commercial varieties are. Mine curl inwards. I put them through the ordinary process—hardening in formalin and squeegeeing on ferrotype plates. Directly they get in the window they curl badly. Can you advise me how to prevent this?—R. N. CLIFFORD.

If you set the cards to dry between two strips of wood placed about  $4\frac{1}{2}$  in. apart, so that the cards are sprung into a low arch, you will find that they will dry almost flat, and will remain so. It is possible you are giving them too severe hardening. Try a 5 per cent. solution of alum for ten minutes. It should be sufficient preparation for the cards before stripping.

**STUDIO QUERIES.**—My studio is 30 ft. long from east to west, and 18 ft. north and south. On the south side is a light starting 6 ft. from the floor, slanting 6 ft. from the vertical up to the ridge, which is 18 ft. above floor level. This light starts 6 ft. from the east end, then glass for 14 ft., leaving 10 ft. blank wall on west end. Marginal sketches show two sections, viz., south side and east end. 1. I note in H. P. Robinson's book, "The Studio," he recommends vertical side lighting, thus avoiding leaks, etc., and states in foot-note some studios have been so constructed. Can you inform me if this method of vertical lighting is a success? If so, by whom, and where? What area of glass would be required to light studio 30 ft. by 24 ft.? Is this vertical system good for large groups? What distance should glass start from east wall? Also from floor? 2. Can you recommend a standard work on this subject other and later than Robinson's? Supposing 24 ft. is too wide to light vertically, would a light like marginal section answer? Or, to put it in other words: How would you light such a studio to get best results? 3. The present system is perfect as far as lighting goes, but as the studio is too small for large groups, it is my intention to increase width 6 ft., and I want to avoid the leaks caused by moss growing in the accumulated dust between laps. I should be much obliged if you would answer above queries. Note: Do not forget this is south of the equator.—JAS. STEWART (Invercargile, New Zealand).

1. Some few studios have been constructed with the vertical light, but this form is now seldom adopted. We should certainly not recommend it for large groups. Neither should we advise the modified form of studio, with vertical light, shown in one of the sketches. The forms of studio most in favour in this country are the ridge roof and the lean-to, both of which are admirably suited for groups. 2. Bolas's book, "The Photographic Studio," is a more recent work, and describes several forms of studios, with cuts illustrating them. It is published by Marion and Co., Soho Square, London, price 2s. 3. As you get on so well with the system you have, why not keep to it, simply making the studio larger? If you are building a new one specially for groups, we should suggest either of the two forms above named.

**FOCAL-PLANE SHUTTER.**—Could you kindly give me a formula in the "British Journal" for making the blinds of focal-plane shutter light-tight? The blind is full of small pin-holes.—W. COOK.

As described by you, the blind requires altogether renewing. We know of no means of usefully repairing it. An odd pin-hole or two can be closed with a tiny patch of thin rubber cemented with a little rubber solution, but in your case you want a new blind. It looks as though an inferior cloth had been used in the first instance.

**W. E. M.**—Of the three, No. 2 is decidedly the best. Of those at ordinary prices, we should advise you to select among Ilford, Barnet, and Wellington, all of which are satisfactory in both the ordinary and the colour respect.

**A. J. REEVES.**—Messrs. Fallowfield. See replies to other queries. **FERROTYPE DRY PLATES.**—Could you inform me through the columns of the "Journal" how to make dry ferrotype plates? Should feel greatly obliged if you could do so.—F. H.

Ferrotype dry plates are prepared with washed colloidal bromide emulsion. But those who produce them commercially do not publish the formula they employ. However, on pages of the "Almanac," you will find formulae which will probably answer your purpose. To fully describe the methods of making the emulsions would take up far more space than can be space in this column. Therefore, we should recommend you to Abney's book, "Photography with Emulsions," through a dealer, or from Dawbarn and Ward, Farringdon Avenue, E.C.4. (3s.)

**FADED PRINTS.**—I am so sorry to trouble you again about the fading of the prints on the mounts. You refer to it as not having been washed before placing in the hypo. bath, but I give the three or four changes, and I also sent the one on the wet mount to compare. The paper used was "—." C.C.M. I also printed on paper, and the toning bath was platinum phosphoric acid. I might also add that only prints put in those certain mounts have faded.—W. S. K.

We are glad to have further particulars from you, though our guess at the conditions under which the prints were made was not far out, we do not think that your manipulation is responsible for the fading. Evidently either the mount or the mount is the cause. You can make sure of the former by using a standard brand, such as Higgins's; and as for the mounts, if the trouble occurs again, we recommend you to the mounts in the following way:—Lay a piece of paper or thin celluloid over half the mount and on this lay an albumen print, finished but unmounted. Pack up with a piece of pure filter paper and several thicknesses of moist blotting paper, put the whole in a printing-frame between glasses to keep in the moisture, and place in a warm place for two or three weeks. If the half of the print in contact with the mount deteriorates before the other the mount is defective.

**A MEMBER OF THE LEGISLATURE.**—We read in the "Manitoba Free Press" that Mr. J. F. Mitchell, who for many years has been a photographer in Winnipeg, is the Conservative representative elected for the division of North Winnipeg. Mr. Mitchell has been for a long time a member of the Winnipeg City Council.

**CHEMICALS IN JAPAN.**—The demand for soda ash, caustic soda, potassium chlorate, etc., in Japan is annually increasing, says "Toyo Yakuho." So far foreign countries have supplied all the chemicals requisite in paper, soap, glass-making, etc., but, as announced in the "Chemist and Druggist" of March 9, p. 36, a company, with a nominal capital of two million yen (£200,000), has been formed to manufacture caustic soda, bleaching powder, calcium chloride, etc., by electrolysis. In view of this fact, the amount of imports in 1905, representing cartons of 1½ lb., may be of interest. Caustic soda—England, 16,987,729; America, 78,131; other countries, 2,630. Soda ash—England, 42,335; America, 16,410,996. Potassium chlorate—Belgium, 42,333; France, 1,042,303; Germany, 1,448,000; and England, 1,960,789. Sodium bicarbonate—all countries, 3,528,000.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears on the last portion of the paper.

## SUMMARY.

Liverpool Society at the Northern Exhibition hit upon an perfect method of displaying lantern slides, using Japanese as a means of diffusing the illumination. (P. 250.)

action of the graphoscope is the subject for an editorial, describes a number of experiments, easily made by any (P. 251.)

leader of the "B.J." in China repudiates the recent allegation the British cinematograph shows in the East are behind those of the production. (P. 262.)

T. Drummond Shiels, in a paper before the Edinburgh Society, recounted some interesting experiences from his professional career, and imparted advice which other portrait photographers may study with profit. (P. 252.)

continuation of the notes on "Spots in Raw Paper," a series of experiments are given serving to identify the more common defects. (P. 254.)

cinematograph water trough and improvements in Dr. Korn's method of electrically transmitting photographs are among the news of the week. (P. 256.)

## "COLOUR PHOTOGRAPHY" SUPPLEMENT.

Ernest A. Burchardt, of the Society of Colour Photographers, has announced to publish the results of experiments in printing with a new method. (P. 25.)

other details of the Traube iodide process are available. (P. 25.)

V. Czapek has completed a series of tests of the Smith "Uto" process. (P. 28.)

the notes are given on the development of three-colour negatives. (P. 29.)

portfolios of the Society of Colour Photographers are now on sale. Some brief criticisms of the contents by Mr. E. J. M. appear on page 31.

## EX CATHEDRA.

### The Iodine Bleaching Solution.

Mr. S. Hall Downing, in a letter on sulphide toning published in our issue of March 29 (where, also, a misprint of sulphite for sulphide should be corrected), gave a formula for an iodine bleaching bath, which formula prescribed the solution of 54 grains of potassium iodide in 4 oz. of water and the subsequent addition of 22 grains of iodine. This is the manner in which the making of the solution is generally described, but it is as well to point out that it is by no means the proper or most convenient manner. It is a slow method, and also a wasteful one as regards potassium iodide, which is rather an expensive salt. From 35 to 40 grains of iodine are quite sufficient for the purpose of dissolving 22 grains of iodine, and the 54 grains mentioned above is a large excess. The proper method of preparing an iodine solution is to weigh out the ingredients separately and then mix them in the dry state. It is best to throw the iodine into a beaker or measure and then spread the iodine over it. If the mass is moistened with a few drops of water and allowed to stand for a minute or so, the iodine is completely dissolved. Water is then added in the required quantity, and the solution is complete. If, on the other hand, the method of our correspondent is adopted, the flakes of iodine take a considerable time to dissolve, and they will not dissolve at all unless a large excess of iodine is present. If the solution is required in a great hurry two parts of iodine can be taken for every part of iodine. One and a half parts of iodine are sufficient, but the solids must then be more carefully mixed if rapid dissolution is desired. In a bleaching bath an excess of potassium iodide is undesirable, as it is a fairly ready solvent for silver iodide.

\* \* \*

### Public Photographic Libraries.

The announcement that the British Museum reading-room is closed until October next will be very unwelcome news to the many students who have occasion to make use of its unique facilities. We believe that provision is to be made for those engaged on important work, but the visitor whose reasons for consulting a volume do not satisfy the officials must seek elsewhere for information. It may therefore be of service to draw attention to the excellent and excellently arranged library of the Patent Office in Southampton Buildings, Holborn, which is open to the public, and contains as complete a collection of photographic books as any institution in London, the Royal Photographic Society, perhaps, alone excepted. The library of this latter body, though for the use of members only, would no doubt be opened to anyone requiring facilities unobtainable elsewhere on application being made to the Secretary at 66, Russell Square, W.C.

### Concerning Lantern Slides.

In our review of the Northern Exhibition at Liverpool we referred last week to the display of the lantern slides, and in the hope that other societies may find our remarks serviceable we return to the subject now. Various as are the methods of showing transparencies, every one is open more or less to the objection that the light may fall towards the corners or the lower line of a group. Reflectors of paper or of mirrors do not afford a perfectly even transmission of light. Mr. John Smith, of the Liverpool Society, tried opal glass in large sheets placed vertically at about 2 in. behind the slides. Through this, however, it was found that the electric lamps were too plainly discernible. He therefore hit upon Japanese vellum paper, such as is used for the printing of engraved plates. This was at once texturous enough to give perfect diffusion, and translucent enough to give a bright and mellow light over its whole surface. Placed in the same position as the opal first tried, it answered admirably. Not one slide was better lit than another throughout a very long series. The densest looked its best, and the thinnest was not garish. Whilst we are on the subject of lantern slides, we may also revert to some remarks by Mr. Tilney in his lecture at the Liverpool exhibition, entitled "Reflections upon the Old Masters." The slides he was using were in many cases badly covered with the stock patterns of masks, regardless of the requirements of the subject. Many fine compositions were ruined by this adoption of the method of Procrustes, who, it will be remembered, cut off at the legs all such of his guests who were too tall for the bed he offered them. Whilst a man may have a right to treat his own creations in any drastic way he pleases, he should certainly respect classic works. A reproduction of a picture fails to deserve the name if its boundaries do not coincide with those of the original. The design is in that case a different one. This principle applies just as much, of course, to the making of blocks as to transparencies.

\* \* \*

### Photographs, Good and Bad.

It is, perhaps, not the most graceful performance to praise your own photographs in public print, even at the editorial bidding, but Mr. Dudley Kidd, who thus, in the "World's Work," instances photographs by himself of South African aborigines, is never undue in the praise he accords to good points in the photographs, and his exposition of a few of the causes which make photographs useless for book illustration deserves to be conned by publishers. Until there exists in every publishing house someone who knows good photography when he sees it, we shall still have to submit to the degradation of the camera which is conveyed in the many books of travel accompanied by "the author's photographs." As we write, a record of an American's Scandinavian tour is before us, with quite fifty plate photographic illustrations, every one of which would disgrace an amateur of a month's experience. It amazes us that any house can waste blocks and paper on such work, particularly when good photographs of all the scenes are obtainable.

\* \* \*

### The Making of a good Illustration.

It is not much that Mr. Dudley Kidd asks for. He only impresses on the tourist that consideration should be given to the lighting and to the surroundings of his subjects—he is writing more particularly of types of people—and that a preliminary photographic "note" should be taken to point out the chief characteristics which are wanted in a given representation. In short, his recommendations amount to the advice which is given to beginners in photography in the better shilling handbooks,

publications which, we fear, are not perused even by those who are embarking on a tour which may extend to thousands of miles and lead them into unexplored parts of the world. In his own especial work of photographing Kaffirs, Mr. Kidd recommends most liberal exposure in order to obtain good negatives of such difficult subjects—a chocolate-coloured native clad in a white nightgown sitting in brilliant sunshine. "Either the face becomes black blot, or the shirt a white glaring mass devoid of trace of limbs beneath it. To further complicate the difficulty, the boy in question was acting as cook, and smeared his face with grease so as to make it shine. The photographer works with an actinometer—and he certainly should do so if he aims at quality—he will find if he gives a 'normal' exposure, the high-lights on the face will become glaring white patches, and all sensible modelling will be lost. In order to avoid these pitfalls it is first of all necessary to give at least ten times 'normal' or 'correct' exposure for the average subject, and secondly, to dilute the developer—in which the exposure must be reduced to a minimum—with four times the usual quantity of water."

### Silver Nitrate as a Remedy for Burns.

Our own experience of the caustic properties of silver nitrate would have led us to have confirmed the statement recently made in one of the leading papers that a strong solution of the nitrate was an excellent remedy for burns. However, we see a German writer, Herr Coblentz, recording his great satisfaction in a solution of this kind as regards its healing properties on skin which has suffered from burns. The writer in question employs a 50 per cent. solution of silver nitrate containing also 20 to 25 per cent of zinc nitrate, the mixture of which is heated to boiling, and while hot brought to the injured place. The first effect of contact with the solution is a smart pain, but after ten or fifteen minutes the pain of the burn commences to disappear, and is completely gone in half an hour, so that only on pressing the skin can a sensation of pain be felt. The scorched skin appears to have been mortified, and in eight days a new skin has formed. It would be interesting to know if the experience of any of our medical readers on the subject of this drastic remedy are similar. The recommendation is one which we cannot remember to have seen in any English publications.

### Photographing Coins and Medals.

A case was mentioned at one of the meetings of the photographic societies recently where the reproductions in a catalogue of a number of medals and coins represented the latter as intaglio instead of as in relief. The effect is not infrequently seen, and is due in most cases probably to the fact that the photographer, when copying the cast of the relief and employing the useful top lighting from the left-hand side, is accustomed to place the cast in an inverted position for the sake of ease in focussing. As a result, a reversed lighting is obtained: the shadows fall, for example, from the upper side of the outstretched arm of a figure instead of from the lower, and the eye, when the reduced coin is observed, attempts to account for the shadow formation by imagining the actual raised portions of the relief as depressions.

### The Action of Thick Lenses.

In an "Ex Cathedra" note in our issue of March 22 we drew attention to the fact that the "nodes," or "principal points," that play such an important part in the Ge-

theory of thick lenses, were referred to and described by Dr. Wood in his "Optics," published in 1818, and we commented on the strange fact that Coddington, in his "Elementary Optics," omitted all reference to these points, though he acknowledged much indebtedness to Wood's "Optics." A further search shows that Coddington remedied this omission in his 1829 "System of Optics," though he appears to have entirely ignored the matter in his 1823 and 1825 editions. It is, however, still more remarkable to find the subject dealt with, very much in Wood's manner, in Harris's "Optics," published in 1775. Possibly Gauss found the germ of his theory in Harris, but the extraordinary fashion in which the theory of thick lenses has been neglected both before and since Gauss's time is anything but creditable. It should be observed that Harris, in describing the properties of the nodes of a lens, does not claim any originality. He rather treats the subject as if it were already a familiar one to optical students. Probably, therefore, it is to be found in earlier books, but so far as we are aware there is no reference to it in Smith, whose "Opticks" preceded the earliest editions of Harris's works.

\* \* \*

**Old and New Authorities.** We have never professed any great respect for the average modern type of English optical text-book, and the little respect we have felt of late has diminished in a most startling fashion. Some recent experimental work led to results that were either quite contrary to the orthodox modern authorities or else quite ignored by them, hence we fell back upon the old authorities, such as Smith, Harris, Wood, Wells, and Young, upon the chance of picking up some evidence corroborative of our own experiments. The result was somewhat surprising, for in several instances we found full details of the very experiments that we had been making, conducted with apparatus constructed in the same way, and resulting in very similar inferences. Moreover, we found a fine collection of simple experiments that are disregarded in more modern books, possibly because they tend to disprove fondly hugged orthodox misconceptions that are necessary to the passing of examinations. It is noteworthy that two of the best of the old writers were more or less amateur opticians. Harris was Assay-Master of the Mint, while Dr. Wells was physician to the Finsbury Dispensary. Naturally, the latter author confined himself mainly to the study of the phenomena of vision, and his essays on the subject should by no means be neglected by the modern student. Harris took up optics generally, but also gave much attention to the subject of vision, and his books are masterly treatises of equal importance with those of the renowned Dr. Smith. The knowledge possessed by both these old masters is astonishing if we compare their works with the poor little compilations that during the last century passed as important and authoritative text-books. Fortunately, there is an improvement of late years, and Mr. Dallmeyer, Mr. Dennis Taylor, and Dr. Sylvanus P. Thompson, with a very few others, have made some very notable additions to our optical literature.

In Chicago there are about thirty process engraving firms, including ten of national note, amongst the largest in America. Some 500 hands are employed—an average of fifty to a firm. So says the Chicago Tribune."

**DANGER OF CELLULOID COMBS.**—An elderly woman, named Ryall, of Camberwell New Road, was lighting a candle, when the flame was blown against her chiffon scarf, and a celluloid comb which she was wearing caught fire. She died in hospital from shock.

## THE GRAPHOSCOPE.

At the end of Dr. Porter's lecture on "Stereoscopy," which he gave at the R.P.S. on January 29, the question of the action of the graphoscope was raised, but owing to the lateness of the hour the matter was not discussed. This subject is one that seems to be very little understood. Everyone who has used the appliance is familiar with its effect, but very few seem to be prepared with an explanation of the relief observed in a single photograph when it is observed through a single large lens. The true explanation is a little complex, as three separate conditions govern the effect, but we hope this article may help to clear up a matter which seems to be one of interest to many.

A graphoscope is a large single lens of sufficient diameter to enable both eyes to observe the photograph, and the three conditions we have referred to are: first, a condition governing the appreciation of perspective; second, a condition peculiar to the formation of a virtual image of a plane object by a single positive lens; third, a condition peculiar to the binocular observation of any diagram or picture through a large lens.

We have several times pointed out the extreme importance of true perspective in connection with the subject of stereoscopy, and also when referring to the matter of monocular relief. The apparent relief due to perspective can only be seen to perfection when the print is examined by one eye from the one proper viewing point, and the trouble with photographs is that the proper view point is very often so near the print that distinct vision from that point is impossible. One remedy for this is to stop down the eye pupil by observing the object through a pinhole. This so increases the range of distinct vision that the proper position can often be found. Another remedy is the use of a magnifying lens to increase the size of the picture, and also the viewing distance, up to a convenient dimension. This, then, is one of the functions of the graphoscope. If the photograph has been produced with a short focus lens of, say, five inches focal length, we can arrange the graphoscope so as to magnify the image twice, and this increases the viewing distance from five to ten inches, which is about the best distance for distinct vision, and enables one to take up the proper view point.

It should be noted that the proper point can generally be found by trial without any calculation, for, provided the photograph is in true perspective, the realistic effect obtained from the one proper point is very striking. One adjustment is so obviously better than any other within certain limits that an approximately correct adjustment is easily arrived at. We advise experiment, first with a pinhole, and secondly with a large reading lens of about  $4\frac{1}{2}$  in. to 5 in. diameter. Such a lens is practically a graphoscope when used with both eyes, and it is a cheap substitute for the elaborately fitted arrangement sold under that name. If the experiments we are about to describe are to be carried out a lens of this description will be necessary. For subject, if no suitable photographs are handy, we would recommend a picture called "Sunlight and Shade" in "The Photographic Monthly" for December, 1906. This shows some excellent perspective and most remarkable relief when viewed in the graphoscope. With this picture and a pinhole the relief due to true perspective is very apparent, and if we examine it with one eye through the centre of the big lens a similar amount of relief is observable.

Now for the first experiment. Mount the picture on a perfectly flat surface, and, examining it with one eye through the lens, find the position in which the perspective looks most realistic. Note that the flat picture has a concave appearance. Next shift the head so that both

eyes can study the picture through the lens. The relief is at once greatly increased. It is much more realistic than before, and, if anything, shows an effect of exaggeration. Moreover, the flat picture no longer appears concave, but most obviously *convex*. If the lens is close to the eyes the convexity is most apparent; in fact, the paper appears to rise up in a great hump in the centre. The concavity seen with one eye is also most obvious when the eye is close to the lens. A further effect to notice is an appearance of cushion distortion. This is evident with either one eye or two, and the effect is precisely similar to that sometimes noticed with photographic lenses, though the cause is a different one.

All the effects noted above are attributable to, and easily explained by, the existence of spherical aberration. Owing to the presence of this aberration the virtual image observed through the lens is a surface convex to the lens. This convexity is apparent to binocular vision, but not to monocular. With one eye there is nothing to denote that the image is really convex. Owing to the presence of spherical aberration the margins of the object are magnified more than the centre, and cushion distortion is apparent; which two effects give the impression of nearness of the margins, and of consequent concavity. This wrong impression is corrected when both eyes are brought into use, and the convexity then becomes apparent, in spite of the fact that the two effects that deceived the single eye are still in evidence.

If the nearest object is in the centre of the picture, as it is in the particular illustration we are using as an example, the evident convexity of the image considerably aids the illusion of relief when we employ binocular vision through the graphoscope. This optical effect, due to the use of an uncorrected magnifier, is therefore a second contributory cause of the effect of relief observed; and we now come to the third cause, which nearly approximates to a stereoscopic condition.

When the relief effect is most obvious through the graphoscope, the simple experiment of opening and closing the eyes alternately will show that the right eye is seeing the subject through the right half of the lens and the left eye through the left half. Each eye is therefore observing through one of a pair of prisms placed base to base, and as a necessary consequence of the spherical aberration that exists each eye sees a differently proportioned picture. This fact will not be apparent in a complex photograph, but it is easily noticeable in a simple diagram consisting of a circle with a series of radii drawn from the centre. This may be looked upon as a plan of a cone. If examined with both eyes through the graphoscope lens the centre will appear to rise up above the plane of the circle, and a cone will be suggested. The suggestion is imperfect, owing to the absence of any perspective in the form of shading, but a conical effect is given. Examine this figure with one eye through the

right half of the lens, and then move the lens laterally so as to obtain a view through the left half. Two obviously different effects are obtained. In both cases the circle becomes approximately oval, but through the right half of the lens the point in which all the radii meet is well to the left of the centre of the oval, while through the left half the same point is well to the right of the centre. Leaving the matter of distortion out of consideration, it is evident that these displacements of the centre point are, very similar to the effects that would exist in a pair of stereoscopic views of an actual cone. The centre point is, in fact, displaced in each view in the same direction as the apex of a cone would be decentred in each of a pair of stereoscopic views; hence the combination of the two views seen through the two halves of the graphoscope gives very much the same effect of relief as that obtained in a stereoscope from two correct views. The result is not accurate, and though the relief obtained is due to the same causes that produce relief in the stereoscope, it is not stereoscopically true. It is, nevertheless, remarkably effective when the subject is a good photograph and the relief of a stereoscopic character is aided by good perspective.

The three causes of the relief observed in the graphoscope are, therefore: perspective, convexity of the image, and differences of a stereoscopic nature between the views obtained by the two eyes. All three causes help in the effect, but perhaps the second one—convexity—might be dispensed with, as it tends to produce exaggeration, and is also sometimes too obvious. It is, however, somewhat advantageous with portrait studies. The effect is generally too obvious when the lens is close to the eye, hence it is best to keep it some little distance away.

An ordinary prismatic stereoscope can be converted into an effective graphoscope by simply reversing the prisms so that their bases are towards each other. Some stereoscopes are so arranged as to permit the reversal of the prisms, and they form very effective instruments for observing single pictures. In the normal stereoscope the prisms are, of course, arranged with their edges towards each other. Each of them slightly distorts the image that is observed through it, but this distortion is just the opposite to that produced with the graphoscope and tends to diminish relief rather than to increase it. If an absolutely correct effect is desired, a lenticular or prismatic stereoscope should be used. It is worth noting that the relief observed in either the stereoscope or the graphoscope is at a maximum when the subject is drawn back from the lens to a distance at which focus is just beginning to be lost. If this distance is too great, the separate images seen by the right and left eyes will jump out of register and cease to combine, just as they do in the stereoscope when the distance between lenses and prints is too small.

## SOME EXPERIENCES OF A PROFESSIONAL PHOTOGRAPHER.

(A paper read before the Edinburgh Photographic Society.)

EVERY business man who deals directly with the public has experiences which are interesting and amusing. The professional photographer has, perhaps, more than his share of these, and, doubtless, many "knights of the camera" could speak interestingly of what they see and hear from day to day. We are told that "the proper study of mankind is man," so it may not be undesirable to look at him as he appears when in process of being

immortalised. Man here does not, of course, refer entirely, even mainly, to the male persuasion, as the photographer's most numerous and most charming patrons are those of the gentler sex. Which is, of course, what should be!

### Men and Women as Sitters.

It might be well to speak first of the difference between men and women from an operator's point of view. A distinguished

operator, from whom I learned much, was often asked by his lady clients if he did not prefer men because they were less troublesome. "Madam," he would diplomatically reply, "while men are certainly easier to photograph, we find the ladies much more interesting." And this is a true statement of the case. It is a well-known fact that expression is the great difficulty in portraiture. Men do not show their feelings in their expression readily as do women, and a moustache often hides the most expressive feature of the face. So that a characteristic portrait of a man is usually not difficult to get.

A woman is more affected by the preparations incidental to the photographing, and, by the time the exposure is made, she is often looking most unlike herself. A tactful operator contrives to minimise the prominence of the necessary preliminaries as much as possible, and seeks to make his sitters feel at ease. But with some people there is always difficulty, and every photographer is familiar with the person who has never had a successful photograph. But, from the fact that they are often difficult subjects, and because of their natural charm and grace, women are always interesting to photograph. But there are more than men and women in the world. There are children—and there are babies! Some people may go through this world unconscious of the fact that there are babies in it, but they are not professional photographers! Something must be said, then, about the photographing of that important personage—Baby.

#### Photographing "Baby."

The scene is an every-day one. The happy mother, after spending perhaps the best part of the forenoon arranging the draperies, vases, etc., so dear to the feminine heart, and so indispensable to every well-regulated baby, bears her precious burden off to the studio. She is full of hope and anticipation that baby will be "so good" and will sit "so nicely." Alas! how frequently those anticipations, coloured by a mother's love, are not realised. How often, after wrestling for an hour or more with one of these little rubs, the poor photographer is left a physical and mental wreck!

In babies, as in most things, we find differences. Some there are with bright, happy faces and flashing eyes, who are full of life and mischief. Others are doleful and melancholy, and seem, from early, to take a pessimistic view of life. All their actions are suggestive of a mind fully alive to the sorrow and vice of this wicked world.

There is also another important difference in babies—the difference of sex. The photographer, after long experience, when taking of the little angel, uses the word "baby," or the safe word "it." The necessity for this is obvious. A sweet little baby lies in, whom, by its mild appearance and artless ways, you are to be one of the gentler sex, and, in speaking to the mother, you say suggestively—"A little girl?" The mother straightens herself up, and, with scarcely concealed scorn in her voice, replies—"No; he is a boy!" Muttering apologies, you retire discomfited, vowing that you will never risk a guess again. I have been informed that the different sexes may easily be told by the difference in the pinafores worn, but this is too dangerous a method for a mere man to venture upon, and he will probably be well advised to avoid it.

Two important considerations in the photographing of babies are mothers. If they and the sundry female relatives who come to take part in the great event could be quietly removed from the room for a few minutes, there would, in most cases, be no trouble. But when the critical moment arrives, and you are engaged to get an exposure, you find that the aforementioned relatives, in various stages of excitement, are vying with you in the effort to attract the attention of that one and only baby. And here, from all parts of the studio, come strange and wondrous suggestions, the object of interest is perhaps deep in the study of the problem of the mysterious world of infancy, and quite oblivious of the commotion of which he is the innocent cause.

Or, again, with wondering eyes, his gaze wanders from one to the other of the gesticulating circle, and, after vainly trying to understand it all, he retires again to the solitude of his own thoughts.

A natural and justifiable weakness of mothers is their undue anxiety as to the likelihood of baby falling. When, perhaps, you are about to open the shutter, the mother, with a whoop worthy of a Red Indian brave, rushes in and saves the child from an imaginary fall. And while you gently remonstrate with her, she is perhaps persuaded to stand far enough away to prevent her also coming into the picture. But the stifled groans and murmurs which come from her direction show how great is the maternal love, and how large a place her little baby holds in the mother's affections and anxieties.

Very often, of course, there is little difficulty in photographing babies. And child pictures are generally very satisfactory and pleasing, because of the absence of the self-conscious expression which is often so noticeable in the portraits of older people.

#### Some Types of People.

A professional photographer comes across many interesting people. There is the man who informs you, with a warning tone in his voice, that he knows something about photography. You are supposed to infer from this that it is no use attempting to deceive him, or to practice upon him any little tricks of trade.

An occasional visitor, too, is the bright little lady, whose deportment does not suggest the stage, who has out out the portrait photographs, and tells you that she knows she is stout, but asks to be taken in a similar position—generally one which is not quite suitable for her.

There are also the people whose features are not exactly Grecian, who insist upon being taken side-face because they have seen a profile of someone else which they admired.

A difficult subject is the elderly lady who comes back with her photographs, and tells you that she knows she is stout, but asks if you think she is really as stout as you have made her.

The man who wants his proofs specially hurried as he is going abroad on the Tuesday, and who comes in on the Wednesday to re-sit, is also sometimes met with.

There is also the person who does not wish to be "touched up," and the person who does not object "to being improved a little." And there is also the person, who is, however, very seldom met with, who does not compare photographing with a dental operation.

Speaking broadly, there are three classes of patrons, which every photographer has, more or less. There are those who like a "clear" photograph, and who wonder why the Colonies produce clearer portraits than we do. These are usually charitable enough in their judgments to put this down to the better light which our Colonial brethren enjoy.

Another class, of advanced artistic taste, prefer low-toned pictures, and do not object to broad effects and a minimum of detail.

And the third class, which includes the great majority of the general public, comes between these two classes. While softness and an absence of glaring outlines are admired, a certain brightness and clearness of detail are also demanded. And it is often a difficult matter for the photographer to reconcile commercial considerations, which demand the catering to different tastes, with the observance of a certain artistic standard. If the commercial side is pushed too far, the artistic side must suffer. And if the desire for artistic effect is carried to extremes, it inevitably means a great narrowing of the circle of possible clients.

#### Outdoor Experiences.

Outdoor work provides photographers with some of their most interesting experiences. Every operator knows that he may expect a funny man in almost every group he takes—the man who raises a laugh at the wrong time. A few quiet words are generally sufficient, however, to cause this individual to subside.

In work done outside the studio, the photographer is frequently hampered for want of time, and he is often not treated with the consideration to which he is entitled. At a marriage party or similar ceremony, he is sometimes kept waiting for a considerable time, and is then told that he can only be spared five minutes for what is usually a difficult piece of work. This is often the result of want of thought and bad arrangements, but it is none the less annoying, and does not give the photographer a fair chance. At other times, of course, it is quite different, and he is given every assistance and ample time, so that the work is really a pleasure.

It is a notable fact in this connection that King Edward treats photographers with the utmost consideration. He is present exactly at the appointed time, and his genial manner and kindly thoughtfulness make him much easier to photograph than many of his subjects.

#### Different Operators.

Photographic operators are themselves an interesting study, and present many different types. Some are meek and patient! At least, I have been told that this is so, and I hope some day to come across one. I have even been told, on good authority, that there are those who will go down on their hands and knees and play with a child for half an hour, just to gain his or her confidence. Such a man is a true artist, and deserves our admiration, but life is too short to allow most of us to indulge ourselves in this pleasant recreation.

Some operators I have known have not been meek and patient—very far from it! They made what seemed to them a reasonable effort to conciliate the affections of children they were photographing. If this had not the desired effect, they retired to the back of the camera, and relieved their feelings in the way men do who feel strongly!

Some operators, again, are very cool and collected (and once more I am speaking almost from hearsay), while others can hardly be so described. An assistant who is working the camera for an excitable operator has no security of a job. His views of the sitter or sitters will probably be only momentary, and when the posing is completed, the operator will express his surprise that his assistant is not ready at precisely the same moment.

One talented operator whom I had the pleasure of assisting had a very restless disposition. When things were quiet, he developed a weakness for painting backgrounds, the troublesome preparations for which I had to perform. After much sketching and colour mixing, the background became a reality. So high was his standard of excellence, however, that the result of his efforts seldom pleased him, and the background had to be taken off the stretcher, put in a tub, scrubbed, and stuck up again ready for a new attempt.

The man who came after him had, strangely enough, quite a

different disposition. The intervals between sitters he spent on a sofa, slumbering peacefully. And, while his energy could not be so much admired, we, as his assistants, found that his habits relieved us of a great deal of mental strain.

Many others could be described, but space forbids.

#### Nature of the Work.

The reasons for liking or disliking photographs are often very curious. Sometimes the photographer is disheartened by the fact that his best efforts do not please. Work which he is proud of turning out is brought back for some trifling fault of dress, or for reasons which are never apparent. One man I remember came to re-sit for his photograph, which was really an excellent portrait. On being asked the reason, he said that, while he and his friends were highly pleased with the photograph, his wife thought she would like to see how he looked with a white tie instead of a black one! In this case, of course, the man was only obeying orders, and could not be blamed. The feminine weakness for detail was alone responsible. Such little incidents develop, or, rather, should develop, in the photographer that supreme virtue—Patience.

However, on the whole, the professional photographer is fortunate in the appreciation which his successful efforts receive. People are very grateful for a good photograph, and the knowledge of this makes a man put forth his best energies to do full justice to his subjects. "Man does not live by bread alone," and this appreciation of success, which is independent of pecuniary considerations, makes the work interesting and attractive. The constant succession of new faces is also extremely interesting, and a student of human nature has abundant material for study.

#### Conclusion.

It is doubtful if the average professional photographer appreciates to the full the dignity of his calling. Photography to-day is an economic and social necessity in every community. It maintains the memory and affections of family life through the picture it makes, and which we could not now do without. How often is regret expressed that no photograph exists of some friend or relative who is no longer with us? Sometimes, indeed, the camera has to intrude upon the sacredness of the death chamber itself, when relatives feel that a photograph in such circumstances is better than none at all.

Portrait photography, altogether, has much of pathos as well as humour in it. Human life is fleeting and uncertain. And it is touching to see an old man or woman, on whose "day of life the night is falling," being brought by the family to be photographed for what must be the last time. Photography is truly

"The Art that secures the shadow,  
Ere the substance vanishes."

T. DRUMMOND SMITH.

## SPOTS IN RAW PAPER.

### II.

#### Methods of Testing Papers of the Kinds of Spots.

No generally applicable method for the certain proof as to the constituents of a spot can be given, even when attention is confined to the above-mentioned cases. It is possible, however, by the systematic adoption of a few simple tests, to obtain important conclusions as to the nature of the spots, which conclusions can then serve to indicate further tests.

The method of investigation to be selected must frequently be decided by the quantity of materials, that is to say, in this case, according to the number of spots and faulty places. The procedure is much simpler when one has so much material that for every experiment new test pieces can be taken than when the same test piece must be used for several experiments.

Below is given the series of tests which can be undertaken with as little material as possible.

Before the tests of the individual spots are commenced, a sufficient number of the spots, which, from their similarity of appearance or frequency of occurrence have to be tested, should be marked with a small pencil cross. If this is omitted it may happen that one may be led astray in the course of the testing, because innocent spots appear more striking than the actual culprits, which sometimes quite disappear.

If one has the whole breadth of the run or large sheets, attention should be directed as to whether the spots occur at definite distances—in the middle or towards the sides of the paper—if also they recur at definite intervals, in the direction of the run.

From such observations the seat of the trouble can be determined frequently more certainly and quickly than by exact cutting of the individual spots. When the spots are marked, they should be cut out so that it is in the middle of about a centimetre of paper. When the appearance of the spots does not make another procedure seem advisable, the following tests should be carried out on these small pieces:—

### A System of Tests.

The spots should be examined in the microscope with about 50-times magnification, without any mounting medium, and their appearance, shape, size, colour, and so on noted. Bronze spots, wood splinters, and colour grains will be at once recognised; fungi can seldom be determined in this way.

1. Treat first with alcohol, then with ether. Spots containing grease and resin will either completely disappear or lose their transparency. Grease spots scarcely change when treated with cold alcohol, but easily lose their transparency after treatment with ether. The resin spots due to the wood-cells dissolve in ether as well as in hot alcohol with some difficulty, and often leave behind a coloured crumbly grain, which consists of gypsum, and which in some cases may also contain sulphurous acid. The spots caused by the gelatine are, as a rule, easily soluble, and seldom leave behind distinct quantities of inorganic constituents. Aniline dyes are notable for the discharge of the colour after treatment with alcohol.

2. The spots which persist after treatment with alcohol-ether should be boiled in water and left in it for some time. Some spots should then be laid on the object-slide and examined in the microscope with a weak power. It should be noted whether the spot forms a depression or an elevation in the paper, or whether it lies in the middle of the paper, or on the upper (lower) (the sieve) side. With the preparing needle one should try to lift the spot out of the paper with as little damage as possible, and place it on a second glass slip. Here it should be spread out by means of the preparing needle, and mixed with a drop of imbedding solution—glycerine, water, potassium-iodide-iodine, zinc chloride solution, etc. Then, after dropping on it a cover glass, it should be microscopically examined. If it consists of fibres, care should be taken to observe whether on or between them there are fungus threads.

3a. If the spots, after treatment with alcohol and water, cannot be dissolved, or are so hard and solid that they cannot be rubbed on the slip, they should be laid for some hours in a 10 per cent. soda lye, washed with hot water, and then the spot can be isolated and distributed and imbedded.

3b. If after treatment with the soda lye the spot cannot be rubbed, the dissolved splinters should be treated for a short time with chromic acid solution on the object slip, and it can then be, if principally of organic substances, easily resolved into separate cells. The chromic acid should be sucked up with a porous porcelain tile, and the fibres microscopically examined in any desired imbedding fluid.

4c. In order to prove the presence of gypsum in a spot, the separated kernel should be heated on the slip with a drop of hydrochloric acid, and an attempt made after drying to detect the gypsum crystals with the microscope.

5. Some of the original spots (or better still, as grease and iron prevent or delay action, some that have been treated with alcohol-ether) should be placed in a dilute solution of ferrous ferri-cyanide of potassium, acidulated with hydrochloric acid, and after about five to fifteen minutes, should be taken up and washed. Iron spots of all kinds will show a blue coloration with this. By using a magnetic steel needle it is easy to determine whether they are metallic iron, hard pieces of iron, or easily broken powder.

6. In testing for iron with the cyanides, it should be noted that unrefined fibres can show a blue coloration if left for long in

the solution, even if they do not contain appreciable quantities of iron.

5. Treatment with dilute iodine solution (strongly diluted solution of iodine in potassium iodide). To prove the presence of starch in spots it is convenient to use the paper treated with alcohol.

### A Test for Sulphites.

To test for sulphites the original paper should be dipped into solution of iodine containing some starch solution—if the paper contains starch the addition of the latter is unnecessary—and then into dilute acid and withdrawn. If sulphurous acid is present the paper itself and the spots will be decolorised. As the decoloration is often only temporary, the behaviour of the paper during the test must be continuously observed. In order to prove the presence of sulphurous acid in the resin spots caused by the wood pulp these should be removed after treatment with alcohol and placed in a test tube with a very small quantity of acidulated blue iodide of starch solution. Decoloration of the iodine solution shows the presence of sulphurous acid. A blank test should prove that the decoloration is not due to the action of the paper fibres on the iodine solution.

6. A thin solution of starch mixed with potassium iodide can be used for the test for free chlorine. As the places containing chloride of lime are not visible, large pieces of the paper should be painted with iodide starch solution, and the appearance of the blue spots noted. The sensitiveness of the reaction is considerably increased by the addition of some drops of dilute sulphuric acid to the starch solution. But with this it should be noted that ferric compounds may also set free iodine and produce the blue coloration. If free chlorine, chloride of lime, is present, the blue coloration will appear immediately, or after a few minutes; if left for some time the paper becomes frequently blue in consequence of the action of air and light without the presence of chlorine.

7. Wurster's Di solution is an extremely sensitive reagent for free chlorine, but also for ozone and hydrogen peroxide. To test for free chlorine the paper should be extracted with cold acidulated water, and to the extract a few drops of Di solution added. In the presence of free chlorine the solution turns red.

8. Solutions of litmus, methyl orange, congo red, phenolphthalein (this last dissolved in water and so much water added that the solution begins to get cloudy) are only used to prove whether the spots show a different reaction from the paper. The solutions should be applied with a tuft of cotton wool. In many cases it is better to lay filtering paper wetted with the solutions on the spots, and then examine them after some time. To test for alkali faintly acidulated congo red solution should be used, only with great care, as it consists of a blue precipitation in excess of a red solution, which stains the fibres of the paper with which it comes in contact so strongly that the blue coloration disappears, and alkali will apparently be proved.

9. Silver nitrate cannot be specially used to prove immediately noticeable faults. The paper treated with a 5 per cent. solution of silver nitrate should be dried in the dark, and then laid over a dish in which there is some iodine solution or bromine water. If after this treatment no spots are made visible, the paper is, after a preliminary exposure, developed and fixed.

10. Damping the paper with alcohol, ether, turpentine, aniline oil, hydrochloric and nitric acid, iodine, bromine, etc. When one has to prove defects which are not visible in the raw paper it is convenient to use gaseous reagents. The paper should be laid on a flat glass dish, on the bottom of which there is a small quantity of the liquid reagent, and then covered with a clock glass with the curved side uppermost. From time to time it should be examined to see whether spots show.

G. DALÉN.

## Exhibitions.

### TASMANIAN CAMERA CLUB.

The International Photographic Exhibition, under the auspices of the Northern Tasmanian Camera Club, was opened on February 14 in the Mechanics' Institute by the Hon. G. T. Collins, M.L.C. There are 700 exhibits from the Commonwealth, New Zealand, England, India, and the Cape of Good Hope. The quality of the work shown (writes a correspondent) is very high, and the expectation of the promoters have been exceeded in the number of exhibitors. The local camera club has competed with first-class men from various parts of the world without disgrace, sometimes, indeed, getting first places. The work sent for show is very fine. A loan collection sent by Mr. J. J. Rouse, of Sydney, attracted much attention. They are large pictures of the Prince and Princess of Wales's tour in India, and were purchased in London by Mr. Rouse. Fifty medals, gold, silver, or bronze, were amongst the prizes given by the club.

The principal prize-takers were as follows:—Open-to-all Section—best picture in exhibition: T. D. Leedham, New Zealand. Next to this came one by Mr. F. Styant Browne, who, however, got first prize for the same picture in the enlargement class. Landscape, open to all: T. D. Leedham and Gordon Montgomery, Ballarat, equal 1; F. Styant Browne, 3. Animals, open to all: Lancelot Usher, Moonah. Tasmanian children, special prize: Charles Davis, jun., Elizabeth Street, Hobart; 1. Seascapes, open to all: T. D. Leedham, 1. Portraits, open to all: Arthur A. Binnie, Dunedin, N.Z., 1; Norman Deck, 2 and 3. Architecture, open to all: F. Styant Browne, 2. Animals, open to all: L. Usher, 1; W. P. Permin, 2; E. G. Gibson, 3. Special silver medal awarded Fred. Marsh, of Clifton, Bristol, England (professional), for flashlight photography. Still life, open to all: Miss Agnes Thompson, Victoria, 1; T. D. Leedham, 2; Arthur W. Walburn, West Hartlepool, England, 3. Open to all colour photography: F. Styant Browne (only exhibitor), 1 and 2. Club exhibits: Working Men's College, Melbourne, 1 and 2; Northern Tasmanian Camera Club, 3. Post-cards, open to all: T. D. Leedham, 1. Section open to club members only—Landscapes: A. H. Hill, 1; F. Styant Browne, 2. Animals: A. H. Hill, 1; Styant Browne, 2. Still life: Arthur Green, 1 and 2; Styant Browne, 3. Portraits: F. Warland Browne, 1 and 3; E. W. Gibson, 2. Seascapes: J. H. Lithgow, 1; F. Styant Browne, 2.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between March 18 to March 23:—

**FIXING BATHS.**—No. 6,451. Improvements in photographic fixing or developing baths. Thomas Jackson, Lloyds Bank Chambers, Cheltenham.

**DEVELOPING TRAYS.**—No. 6,613. New and improved skeleton tray for use when developing photographic plates and the like. Michael Paris Foran, 18, Southampton Buildings, London, E.C.

**MULTIPLE APPARATUS.**—No. 6,739. Improvements in multiple photographic apparatus. Robert Bachstein and Baldwin Emil Enge, 31, Bedford Street, Strand, London, W.C.

**ROLLER-BLIND SHUTTERS.**—No. 6,785. Improvements in roller-blind shutters for photographic cameras. The Thornton-Pickard Manufacturing Co., Ltd., and George Arthur Pickard, 6, Bank Street, Manchester.

**LANTERN-SLID STORAGE BOX.**—No. 6,794. Improved changing and storage box for lantern slides. Herbert Holmes and Houghton's, Ltd., 88, High Holborn, London, W.C.

**PROJECTION LANTERNS.**—No. 6,846. Improvements in magic lanterns particularly applicable to advertising. Jacob Christian Grassmann, 7, Southampton Buildings, London.

**CAMERA STANDS.**—No. 7,017. Improvements in attachment devices for holding or supporting hand or other photographic cameras. Frederick Vivian Thompson, 33, Chancery Lane, London, E.C.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**CINEMATOGRAPH WATER TROUGH.**—No. 5,626. Water troughs for absorbing the heat rays have been used in cinematograph and other apparatus for the purpose of reducing the heat on the film or other object projected. Such troughs have had certain disadvantages such as the production of air bells on the glass, the liability to over heat and leak, great absorption of light and difficulty of transporting the same.

The object of the present invention is to overcome these disadvantages.

A much thicker water trough is used for absorbing the heat rays, and condensers of suitable curves arranged in conjunction with the same whereby the spherical aberration of the condenser is partly corrected and the loss of light by absorption is more than counterbalanced. The trough may be formed with parallel ends.

The surface of a condenser may be used to close one or both ends of the trough in place of the parallel glasses hitherto used, thereby saving reflecting surfaces and the consequent loss of light.

Fig. 1.

The trough is formed with a metal tube which may be parallel throughout its length or of conical form but of such size that all the rays of light pass there-through and at the ends of metal tube are fixed the lenses or plain glasses. Such tube is surrounded by a water jacket preferably of length equal to the metal tube.

In order to prevent the formation of air bells on the surface of the lenses or plain glasses, the water used in the interior of the metal tube has been previously boiled and filtered.

One can easily carry the small quantity of boiled water or other liquid in the metal tube, which tube may be hermetically sealed provided means are allowed for expansion of the liquid.

One method of carrying the invention into effect is illustrated in the accompanying drawings in which fig. 1 is a central longitudinal section of the complete apparatus and fig. 2 is a rough diagram showing how the spherical aberration of the condensers is partly corrected.

*a* is the water trough which is much thicker than heretofore so as to contain within its body those points at which most

Fig. 2.

of the rays passing through the condenser would be focussed if the water trough were not present.

Within this water trough *a* is fixed a metal tube *b* which is shown of conical form but which may be parallel throughout its length. One end of this metal tube *b* is closed by the condenser lens *c* of any usual construction and the other end is closed by a plain glass *b^1*. The metal tube *b* has two filling

and expansion tubes  $b^2$  the upper ends of which may be connected and closed by an india rubber tube  $b^3$  which allows for expansion.

The metal tube  $b$  is filled with boiled and filtered water or some other suitable liquid which liquid can be carried about in said tube or in another receptacle. The trough  $a$  may however be filled with unboiled water which can generally be obtained at any place where the apparatus is used.

Referring to the diagram shown in fig. 2,  $d$  represents a point of light.  $e e$  represent in dotted lines two marginal rays which would be refracted to the point  $e^1$  if refracted through air.  $f f$  represent in dotted lines two other rays passing through the lens  $c$  nearer to its axis. These rays  $f f$  would be refracted in air to the point marked  $f^1$ . However, when the rays  $e$  and  $f$  are refracted as shown in full lines through the denser medium of water they are not refracted to the same extent and

cell with two working batteries 9 and 20, while the juncture 17 of both selenium cells is connected with the juncture 18 of both working batteries by means of a sensitive galvanometer, which actuates an automatic device for subjecting the second selenium cell 19 to the same degree of exposure, substantially as set forth.

2. The method according to Claim 1, in which the automatic device consists of a Wheatstone bridge comprising two like selenium cells 26 and 27 and two like batteries 28 and 29 connected in series, these two selenium cells being exposed by means of the sensitive galvanometer 11 in proportion to the variation of the exposure and the second galvanometer 33 being controlled for equalising any difference between the exposures of the two and adjustable resistances, substantially as set forth.

3. The method according to Claims 1 and 2, in which the selenium cells are each replaced by a system of selenium cells and adjustable resistances, substantially as set forth.

Fig. 2.

consequently the points corresponding to  $e^1$  and  $f^1$  more nearly coincide as shown in the diagram at or near a point  $g$ , or at some other one point as is well understood.

All the rays passing through the condenser are more perfectly focussed to the same point instead of being focussed to different points such as  $e^1$  and  $f^1$  by which means the greater loss of light due to the rays passing through a thicker water trough than heretofore is to some extent compensated by the more perfect focussing of the rays.

In the example shown in the drawings the lenses are made of crown glass, having a refractive index of about 1.5, and are of 4 inch diameter, of plano-convex form, the convex surface having a radius of 3 inches. The length of the water trough is about 14 inches. The apparatus is suitable for use with an arc lamp carrying 30 amperes of current.—Arthur Samuel Newman, Linden Mansions, Highgate, Middlesex.

PHOTOGRAPHY.—No. 16,343, 1906. The invention consists of means of measuring the degree of exposure of a selenium cell, whereby it is rendered possible to produce improvements not only in photometry, but also in phototelegraphy, and in their applications for which the invention may be put. The claims are:—

1. The method of measuring the degree of exposure of a selenium cell, which consists in rendering the time variations of the conductivity of the selenium cell that do not correspond

Fig. 1.

the variations in the intensity of the light, inoperative for the action of a galvanometer, 33 indicating the degree of exposure of the said selenium cell, in the manner, that a second like selenium cell 19 is connected in series with the said selenium

A useful application of my invention is phototelegraphy, which may be arranged as follows:

The camera obscura containing the lens 6 and the selenium cell 8 is provided with any known device for gradually and successively moving a transparent original 7 (such as a photographic negative or the like) through the focal point in fig. 1 in two directions at right angles to each other. The selenium cell 19 is provided with a hole 48 and behind this cell 19 a suitable camera obscura (of which only the front wall 49 is shown) is disposed. Within this camera obscura a cylinder 50 is mounted to turn and to longitudinally move, any known mechanism being employed for moving the sensitive film placed round the cylinder 50 synchronously with the original 7 at the distant station. Of course the front wall 49 of the camera obscura is provided with a fine hole in line with the hole 48 in the selenium cell 19.

Fig. 3.

Fig. 4.

This system operates as follows:

5 denotes a suitable source of light, which emits a pencil of rays of light through the lens 6 and the focal point towards the selenium cell 8. Of course this pencil of rays of light will be more or less weakened by the opaque parts on the original 7, after which the rays of light act upon the selenium cell 8 for more or less reducing its resistance. In accordance therewith also the resistance of the other selenium cell 19 will be more or

less reduced and the cell 19 itself will be exposed to rays of light of a varying intensity as explained above. During the motion of the original 7 through the focal point the intensity of the ray of light passing through the hole 48 in the selenium cell 19 and that in the casing 49 and acting upon the sensitive film on the cylinder 50 will vary in correspondence to the several points of the image, picture or the like to be transmitted. The image produced in the sensitive film on the cylinder 50 acted upon in this manner can be developed in any known manner.

The sensitiveness of the galvanometer 11 is so great, that its arm 14 will already travel the path from the one stop 15 to the other one 16 or *vice versa*, if the frame 12 is passed through by a current of a strength less than one twentieth of the maximum, while the full exposure to the pencil of rays of light reflected from the mirror 13 will change from the selenium cell 25 to the other selenium cell 27 or *vice versa*.

It is assumed the system shown at fig. 2 comprises four simple selenium cells, but it is evident, that each of them may be replaced by a system of selenium cells and resistances, for example by a selenium cell 41 connected in multiple with an adjustable resistance 42 as shown in fig. 3, or by two selenium cells 43 and 44 connected in multiple with an adjustable resistance 45 as shown at fig. 4. Thereby it is rendered possible to adjust the resistance of each selenium cell to a nicety.—M. Arthur Korn, 1A, Hohenzollern Strasse, Munich, Germany.

### New Trade Dames:

**KLINITE.**—No. 290,661. Chemical Substances used in Manufactures, Photography, or Philosophical Research, and Anti-corrosives. Waldberg and Co., Gesellschaft Mit Beschränkter Haftung, 5B, Universitäts Strasse, Berlin, Merchants.—February 22, 1907.  
**GLAZIDE.**—No. 290,519. Photographic Paper. William Jones Williams, 42, Rutland Park Mansions, Willesden Green, London, N.W.; Accountant.—February 16, 1907.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Developing P.O.P. Prints.

Before commencing work (writes A. W. Winter in "The Amateur Photographer") prepare a small quantity of a saturated solution of potassium bichromate, and with this make up the following bath:—

Potassium bichromate (saturated solution) .....	20 minims.
Strong hydrochloric acid .....	10 drops.
Water .....	10 oz.

This mixture has powerful oxidising properties, and serves to destroy too readily reducible silver salts in the paper.

After taking the print from the printing frame, wash it in a good stream of running water for at least fifteen minutes. I have tried washing in changes of water, and in salt solution, but neither appears to be effective.

When this washing is complete, transfer the print to the dilute chromate solution given above, and allow it to remain therein, with occasional rocking, for one minute; then wash in six quick changes of water, and proceed to develop in the ordinary way.

The developer I used was dilute rodinal, and the colour of the image a greenish black; it is quite possible, however, that by employment of a developer suited to gaslight papers, e.g., amidol, a good black tone might be obtained directly.

### Bromides as the Starting-Point for the Oil Process.

The blending of two such antagonistic modes rather pleases me, writes Mr. Robert Demachy in the "Amateur Photographer" for April 2, and I confess that the idea of subjecting the cathodic bromide surface to the heretical contact of the oil stencilling brush first tickled my sacrilegious fancy. It is done thus: Take a bromide print, sensitise it with bichromate solution, dry in the dark, and print in diffused light after carefully registering print and negative.

I believe it will be necessary to add that the same negative from which the now sensitised bromide has been printed should be chosen in preference to any other. This for the unsophisticated reader who still believes in the eccentricity of the pictorialists. After

exposure wash in cold water, soak in lukewarm water for a few minutes, and proceed to ink in the habitual way.

There is less liberty of treatment with the visible bromide than with the colourless relief of pure bichromated gelatine. In the latter case we start from absolute white, and can go right up to absolute black; in the former we only have at our disposal the gamut of tones exceeding that of the bromide image, and its highest whites are our highest whites. We cannot add lights, but we can intensify the existing light tones by the added contrast of deeper blacks. Unhappily, there is no possibility of actual suppression by non-inking, though we may hide certain objectionable features by over-inking with thin cils. Really our work is somewhat like the classic mercuric intensification, but with this serious advantage, that it can be applied locally, and may be applied artistically. Moreover the oily nature of the added pigment imparts a new depth to the image, which becomes infinitely superior in quality to the primitive bromide surface.

### Preservation of Developers.

So far as the solution itself is concerned, says Mr. Chapman Jones, F.I.C., writing of the preservation of developing solution in the "Practical and Pictorial Photographer," and regarding its preservation, it should be concentrated and acid, because under these conditions it absorbs oxygen more slowly, and apparently in a smaller proportion. The best acid to use is sulphurous—not the solution of the gas that goes commercially under that name, for it is not dependable with regard to either strength or purity, though it may be excellent when bottled up by the maker. An acid sulphite should be used, and of these potassium or sodium metabisulphites are doubtless the best of those readily obtainable. If neutral (ordinary) sodium sulphite is used, this may be acidified with almost any acid, but then a fresh salt is introduced which may not be without action. Sodium sulphite with sulphuric acid gives an acid sulphite and sodium sulphate, and the sulphate is certainly not advantageous even if it does no particular harm during development. If citric acid is added sodium citrate is produced, and this is a notable and useful restrainer, good if needed, but not always required. For the acid sulphites lead to the production of nothing but sulphites

## New Books.

**FOCAL-PLANE PHOTOGRAPHY.**—Our fears for the demise of the excellent photographic periodical, "The Photo-Miniature," which for some months past has failed to reach our table, are dispelled by the arrival of No. 77 dealing with focal-plane photography. A number of writers deal with various aspects of this present-day question, in regard to which there is a unanimous chorus of prayer for the focal-plane shutter. The number, which is obtainable from Messrs. Dawbarn and Ward, 6, Farringdon Avenue, London, E.C., price sixpence, contains also many striking examples of high-speed and low-speed focal-plane work, together with two supplementary tables, one giving the equivalent exposures with different diaphragms and the other exposures for moving objects at various distances. The volume should be perused with interest, not to say profit, all having occasion to use a focal-plane shutter.

**"PICTORIAL LANDSCAPE PHOTOGRAPHY."**—Under this title are collected five chapters on outdoor photography by Mr. J. C. Warburg, constituting the fifth volume of the photographic manuals issued by our contemporary, "Focus," price sixpence. Mr. Warburg, always precise, communicates a good deal of information of a practical kind within the fifty pages at his disposal. He reserves the last page or two for an appeal to the esthetic sense of the reader, concluding: "Above all, be true to yourself. So may you add to the world's store of beautiful things and help photography along its difficult path of art." An altogether excellent little book.

**"CAMERA WORK."**—The current issue of Mr. Stieglitz's quarterly, which has just reached us, has as its most notable contents a selection of the pictorial work of Mr. George Davison. The fine reproductions are photogravures of Messrs. T. and R. Annan, and we wish that his official duties left Mr. Davison more time for his own photographic work. His "Onion Field" and "Long Arm" are among the subjects reproduced, and many on that account we no doubt be glad to have the issue of "Camera Work."

## New Apparatus, &c.

Thornton-Pickard "Folding Ruby" Hand Camera. Made by the Thornton-Pickard Manufacturing Company, Altrincham, Cheshire

In reviewing recently the new model of the "Royal Ruby" camera of the Thornton-Pickard Company, we drew attention to great improvements recently introduced by the makers into that instrument. These improvements centre in certain mechanism which permits of a larger front or lens panel being given to the camera. Precisely the same advantage is possessed by the "Fold-

Showing rise of front by means of independent rising panel:—Lens at extreme top of plate.

"Ruby," a hand camera of the very widest capabilities, which practically a self-contained version of the stand instrument which we have already described. The two figures which we give scarcely convey an adequate impression of the wide range of movements. They illustrate, however, a very essential part of the camera, namely, the double-action rising front, by which a very great amount of rise may be obtained, not only at the normal extension of the

Shortest Focus,  $2\frac{1}{2}$  in., showing great rise obtainable in this position by independent panel.

camera, but also when a wide-angle lens is being employed. The range of up (and down) movement is obtained by raising the front whole on the struts and afterwards by still further elevating the lens on the divided panel. For this latter movement a very convenient rack and pinion adjustment is provided.

The range of movement rendered possible by the universal swing will be understood by those who read our previous notice. The other features of the camera need only to be briefly epitomised on account of the suitability for all classes of work and its convenience and comfort in the hands of the user. It possesses a dropping

baseboard for use with short focus lenses, it has an expansion of 15 in. in the quarter-plate size, reversing back, and automatic snaps for such parts as the dark-slide runners, the swing front and infinity adjustment so that a great part of the need of looking to the proper fixing of the camera is done for the user. One other point, the smoothness of the exterior and its freedom from screws and catches, is deserving of a special mention. The price of the camera is £6 10s. in the quarter-plate size, with three double dark slides, Thornton-Pickard Panoptic shutter, spirit level, and Beck R.R. lens. In the 5 x 4 size the price of the set is £7 10s.

**THE ISOSTIGMAR LENS.**—Messrs. R. and J. Beck, Ltd., 68, Cornhill, E.C., are quickly in the market with their new "Isostigmat" lens, the new instrument which possesses theoretical interest in addition to its high optical perfection. During the present month they offer a number of Isostigmars fitted with Celverex shutters at greatly reduced prices—e.g., £1 17s. 6d. for the quarter-plate lens and shutter, instead of £3 7s. 6d. Announcement of Messrs. Beck's offer appears in our advertisement pages.

## New Materials.

**SEMI-GLOSSY BROMIDE PAPER.**—A new brand of bromide paper has been placed upon the market by the Bayer Company, 20, Booth Street, Mosley Street, Manchester. It possesses a very fine-grained surface, approximating to that of albumen paper. The makers, in their circular of instructions, recommend edinol developers, and a fixing bath of hypo and acetone sulphite.

## CATALOGUES AND TRADE NOTICES.

**MESSRS. J. LANCASTER AND SON, LTD.,** whose new address is Camera Buildings, Broad Street, Birmingham, have sent us a copy of their latest catalogue of photographic apparatus, the 72 pages of which are crowded with useful information respecting the well-known Lancaster specialties, each article being illustrated and accompanied by descriptive letterpress. The items are too numerous for us to mention individually, but the booklet is well worth perusal, and Messrs. Lancaster will send a copy to those of our readers who apply for same.

**ORTHOCHROMATISM FOR BEGINNERS.**—We welcome the publication, by Messrs. Wratten and Wainwright, Ltd., of a brief and lucid treatise on the elements of orthochromatic photography. After a short exposition of the principles of the subject, a number of useful hints are given on the use of orthochromatic plates for various classes of work, concluding with some tabulated information as to the selection of plate and screen when employing panchromatic plates. A number of useful notes are also given on development, including the employment of the "time" method. Messrs. Wratten and Wainwright will send the booklet free to any photographer on application.

**THE "BIRDLAND" CAMERA.**—A new booklet of this well-known reflex camera, designed by Mr. Oliver G. Pike, has been issued by the makers, Messrs. Sanders and Crowhurst, of Shaftesbury Avenue, London, W.C. It contains some interesting notes on natural history photography by Mr. Pike, together with a number of reproductions of photographs by the author and other users of the "Birdland." The booklet deserves to be in the hands of those intending to purchase a high-class reflex camera.

**THE VANGUARD MANUFACTURING COMPANY,** Maidenhead, notify us that, by courtesy of Messrs. Wellington and Ward, they are able to send a cabinet portrait study upon Wellington cream crayon bromide paper, toned in the Vanguard "Bertha" sepia toner. The sample before us is an admirable example of what a sulphide toned bromide should be.

**MESSRS. JAMES WOOLLEY AND CO., LIMITED,** of Victoria Bridge, Manchester, send us a copy of their 1907 "Photo Handbook and Catalogue," which, in addition to particulars of the various goods sold by this firm, contains hints to the beginner as to the purchase of his photographic outfit, etc. A copy of the booklet will be sent, post free, to any of our readers, on application to the above address.

## Meetings of Societies.

**CROYDON CAMERA CLUB.**—"Orthochromatics" once again held the field last week, Mr. F. Hicks contributing a paper on the subject from a pictorial point of view, Mr. Terry illustrating the ease and certainty with which panchromatic plates could be developed in total darkness. Mr. Hicks was of the opinion that the correct record in monochrome, of the relative brightness of objects as seen by the eye, if the ideal from the scientific point of view, was not necessarily essential, and in some cases might be even detrimental, from the pictorial aspect. What should be striven for rather should be a harmonious and pleasing result, regardless whether it was a correct monochromatic translation or not. Orthochromatic plates and filters were by no means a short cut to the attainment of pictorial triumphs, though many might be led to believe so. The retention of cloud forms was an advantage in some cases, but if unsuitable, the mere fact that they were true to nature, formed no excuse for their existence in the picture. For landscape work he had come to the conclusion that a strong cutting filter was generally speaking undesirable, as having a distinct tendency towards killing atmosphere, and obliterating distance. On the other hand, for cloud work pure and simple, he had found a strong cutting filter, in conjunction with a panchromatic plate, secured the beautiful modelling and soft tracing of cloud forms with aerial perspective, so often the making of a picture. For sea and marine work the same plate and a medium screen (Wratten 8 x 4 screen) were very effective. In his, the lecturer's opinion, thanks to the plates now on the market, largely more sensitive to yellow than to blue, fair correction on ordinary subjects would be attained without the use of a filter. With screened plates great care should be taken to obtain approximately correct exposure. An actinometer should certainly be used, but the sensitive

paper employed for gauging the light left plenty of room for improvement. This was especially the case in weak and yellow light. An undoubted tendency of screened plates was to emphasise heavy tonal grounds and shadows. This might possibly be due to the steep gradation obtained. However, whatever might be said "for and against," the panchromatic plate and adjusted filter had come to stay. In many directions it undoubtedly scored, and for open view the combination was unsurpassed.

In the discussion which followed, some interesting points were raised. Mr. W. C. Woodland said he had read a letter from Mr. Watkins, recently appearing in *THE BRITISH JOURNAL OF PHOTOGRAPHY*, commenting on some statements made at a meeting of the Croydon Camera Club. Mr. Watkins claimed certain orthochromatic properties for his "steadfast paper." He, the speaker, as suggested by Mr. Watkins, had exposed the paper behind a Chapman Jones plate tester, and whilst it was true that the red and green squares gave about the same reading, yet the sensitiveness of the paper to these colours, as compared to blue, was roughly the ratio of 256 to 1. The orthochromatic properties of the paper were therefore not remarkable. In answer to a point raised by Mr. H. Allen, Dr. Meade said that the conditions necessary to prevent mottling of the film stand development in flat dishes were: (1) the plate must be perfectly level, and (2) the strength of the developer so adjusted that development should not be completed under fifteen minutes. The evening terminated with a brisk argument on the gradation, latitude, and ratio values of orthochromatic plates, and a hearty vote of thanks to the joint lecturers.

**SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.**—At Wednesday's meeting of the organising committee of this society, Mr. A. Haddon was in the chair, and on the motion of Mr. J. Nixon, the committee rescinded its previous decision to put off the question of financial arrangements till the first general meeting of the society. The crucial question settled, Mr. Nixon was unanimously re-elected secretary, and promised to do his best to make the society a success. A supplementary club was thereupon constituted to raise the capital to provide premises, furniture, and apparatus. As organised, the club will consist exclusively of members of the photographic society who subscribe for one or more five shilling shares, and it will be registered so as to limit the liability of the members to the amount actually subscribed. The photographic society will thus start free from any burden of debt, and will simply pay an inclusive rent for the club for the facilities provided. The provision that no person who is not a member of the photographic society can hold shares in the club, and that every member of the society is entitled to become a shareholder in the club, also secures to the photographic society full control over the financial arrangements, and prevents the financial control from getting into the hands of any clique. The meeting also appointed sub-committees to carry out the details of the decision, and to select the necessary furniture and apparatus to enable the society to start work in April, as originally intended. Major Coates, M.P. for Lewisham, having been invited to accept office as a vice-president, is now considering whether he can accept the invitation. He is president of the Catford and Forest Hill Photographic Society, and in writing to the hon. secretary of the South Suburban Society, expressed a hope that the two societies will be able to amalgamate, as originally suggested. We understand the South Suburban Society already numbers over six hundred members.

## Commercial & Legal Intelligence

**A TROWBRIDGE BANKRUPTCY.**—Edward George Shotter, 85, Palace Street, Trowbridge, Wilts, photographer, formerly of Salisbury, Frome, and Gloucester, appeared for his public examination at the Bath Bankruptcy Court last week before Mr. Registrar Robertson. The statement of affairs filed by the debtor disclosed unsecured liabilities amounting to £142 1s. 9d., and assets (a cycle) £2. The Official Receiver's observations debtor was said to be 29 years of age, and stated that he began business in December, 1904, as a photographer at Winchester, without capital, and had since resided at Gloucester, Frome, Sutton-in-Ashfield, Kirkby-in-Ashfield,

ding, and Trowbridge. In answer to the Official Receiver, debtor before he became a photographer he was an insurance agent, and a little stock-in-trade, which he obtained during his practice as an amateur photographer. Through a fire he lost between £200 and £250. He was not insured. He sold the business at Frome for last June. With regard to this and the disposal of other businesses, the debtor was closely examined. The examination was held.

#### NEW COMPANIES.

**CURRIE AND CLIFFE, LTD.**—Registered March 19. Capital: £1000, in £1 shares. Objects: To take over the business of art photographers carried on by M. H. E. Currie and P. Sutcliffe, at Plymouth, as Currie and Cliffe, and to adopt an agreement with said vendors. No initial public issue. The first directors (to be not less than three nor more than five) are: M. H. E. Currie (managing director), Annie L. Currie and P. Sutcliffe. Capital: £50. Registered office: 16A, Brunswick Street, Plymouth, Devon.

## Correspondence.

- *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*
- *We do not undertake responsibility for the opinions expressed by our correspondents.*

#### BLISTERS ON BROMIDES.

To the Editors.

Gentlemen,—Mr. Gallagher offers a "specific cure" for the above, I fear the matter is not one which may be dismissed so easily. As a chemist of over thirty years' training, I have a tendency to methodical working—with due regard to temperatures—and a special respect for clearing and hardening baths. I cannot bring myself to look upon "a handful of alum in my fixing bath," which would be one part to anything you wish, and is certainly no information of business value—as a legitimate cure for the complaint. To an extent, the reason of the blistering is a mystery, e.g.: One may work for months at a time with no particular regard to temperatures and fresh baths, etc., and actually forget that you had any experience of blisters, then all at once the epidemic breaks out. (b) Two operators may be working together, and one will have blisters while the other has none, using the same solutions and washing water. This is an actual fact. (c) Alum (or saline baths) before and after fixing is not an absolute cure. The fact of a bromide print not blistering in a hypo alum bath proves nothing, as the same print might not have blistered in the ordinary bath. (e) Out of twelve prints exposed one after the other taken consecutively from one package, three or four may blister, while the others will be perfect. (f) Thick and rough paper never blisters, in my experience—blisters, intimating that the density of the print may be a safeguard, but Mr. Gallagher says bromide prints blister especially! It is clearly impossible to draw a straight line through all these conflicting conditions. I think we shall find a solution of the mystery not so much in the temperatures of baths, which, naturally, the photographer (not being an unmitigated ass), keeps as nearly uniform as need be, so much in baths of average freshness and strength, alum, etc., as in some fault in the gelatine used in making the emulsion—that is to say, the cause is some fault which is not to be laid upon the shoulders of the paper. Now, it would surprise me if several hundreds of yards of paper could be made uniformly thick or thin throughout the whole of its length. It would not be unreasonable to expect what we may call "flats" here and there, not numerous, nor large. Again, an emulsion be evenly spread over an uneven surface? We must imagine the fault to be very small—one "flat" in a

surface 30 ft. by 30 in. would be enough; but realise that the emulsion might not make quite such intimate contact there, and you may look forward to a blister.

A slight accidental error in drying the paper might have its due effect in the same direction, and, above all, we might say that if the fingers are ever used in very occasional passages—mere smoothing touches on the moving surface of the support—then the cause may again be suspected.

I have used the sulphide toning bath with a good measure of success—I refer to Mr. Blake Smith's formulæ. The other day, after toning two bromides 24 x 20 (on rather thin but rough paper) successfully, I took in hand four 15 x 12 size, using the same baths. Three out of the four blistered badly in the first washing water; all had been subjected previously to a hardening bath.

I fear, after all, I have not thrown much light upon the mystery of the blister fiend, but I am more than ever convinced that the fault is not one to be laid upon the operator nor the chemicals—nor even the temperatures.—I am, Gentlemen, Yours, etc.,

Nottingham.

J. P.

#### BUSINESS METHODS IN THE STUDIO.

To the Editors.

Gentlemen,—I do not claim to be the originator of the columnar cash book. As an accountant's method it has doubtless been in existence longer than I have.—Yours faithfully,

309, Regent Street, W.

C. H. HEWITT.

To the Editors.

Gentlemen,—With reference to your articles dealing with "Business Methods in the Studio," and the letter from your correspondent "Rutts," we beg to enclose you a sample leaf of our special summary book, which we published some years ago, and which is designed by a practical accountant for the exact purpose you advocate. This book gives a complete dissected record of the whole working of a photographic business, and a very valuable feature is the summary at end and the formal balance-sheet. It is so simple that anyone can keep it. Unfortunately the average photographer seems, as you say, to neglect a proper system of book-keeping but we could easily get testimonials as to its efficiency from those who have used this book for years.—Yours faithfully,

DE GRUCHY AND CO.

Reliance Paper Works.

45, Mitchell Street, London, E.C.

March 26, 1907.

[We are glad to draw attention to Messrs. De Gruchy and Co.'s publication, which appears admirably adapted to its purpose.—Eds., "B.J."]

#### PROFITS ON PICTURE POSTCARDS.

To the Editors.

Gentlemen,—I am obliged to Mr. Corkett for his estimate of charges for negatives to publishers by local photographers for reproduction purposes, and consider it reasonable, though I have found even the most wealthy firms complain of paying 10s. 6d. for the right to reproduce from picked negatives, which is equal to paying for negatives taken to order; in many cases they are better than could be re-taken, except at specific times.

I ought also to be obliged to "Postcard" for enlightening my darkness respecting his term of "printing postcards in the camera." I had never heard the phrase used for reduction in the camera, and, as he says, it seems ridiculous that any photographer should waste his time in multiplying postcards by so slow a method for such a result; but when I read "Postcard's" letter enlarging on the benefits of the process-printed card I was reminded of a letter that appeared in the "B.J.P.," probably six or seven years ago, signed "Postcard," which also was in a similar strain, and which I found a traveller from a well-known process-printing firm calling on me shortly after produced in circular form as an evidence of the monetary value of the picture postcard so produced. Hence, perhaps,

I was a little more sarcastic than I might have been; but memory sometimes reproduces facts which appear grotesque.

PROFESSIONAL.

To the Editors.

Gentlemen,—I have been much interested in the correspondence, re "Postcards," appearing in the "B.J.," particularly the question of price to charge publishers for taking negatives for their own series of cards. I very much question whether any photographer would be able to demand a fee of 10s. 6d. per negative for half-plate size, especially when a number are taken at the same time. I have taken some two or three hundred negatives, half-plate, both for local publishers and publishers in the neighbouring town, and although not "a small amateur professional sort of a man," I have not been able to get more than 2s. for each negative—that is, taking a series of a dozen upwards at one time. I find this to be about the average rate, and if the local photographer is not willing to do the work at this price, it is very easy for the publishers to find someone who will; in fact, most of the town publishers will send out their own photographers. What chance, then, has the local man to demand anything like a remunerative price?—Yours truly,

ANOTHER POSTCARD.

To the Editors.

Gentlemen,—Referring to Mr. Corkett's letter in your issue of March 22, I am quite in agreement with him as to the scarcity of good landscape photographers, in which category I include topographical work suitable for postcard and guide-book illustration. But I should like to hear where the editor is to be found who will prefer good work, involving the unavoidable extra expense in time, etc., to the ordinary thing on the cheap.—Yours faithfully,

25, Rosendale Road, Dulwich.

J. A. C. BRANFILL.

April 2, 1907.

#### BRITISHERS NOT ASLEEP.

To the Editors.

Gentlemen,—In your issue of December 28, which was lately to hand, I read a most extraordinary letter under the heading of "Britishers—Wake Up!" As a showman in the East for sixteen years, I can hardly pass such a bunch of wild statements unchallenged. For my own part, I have never seen the rough shanty or canvas tent show run by an Englishman. As you are probably aware, all is not English in the East that sports an English-written signboard. It has never been my luck to meet with either a Chinaman or a Japanese who knew the first thing about an animated picture exhibition, and I have seen quite a number. Their shows were chiefly to be remembered by the breaking of films, popping of the jet in the case of limelight, a wild attempt to focus the arc, resulting in a dark grey disc or a composite picture of moving film and some of the spectrum, in the case of electric light, and frequent intervals of darkness. Unsteadiness and flicker I will not speak about, as I never stayed long enough to get used to them. Native music can only be described as an "infernal din," and would drive any Englishman out quicker than a loaded gun would. But perhaps your correspondent is a Scotchman?

I'll guarantee the fiddle did the same old wail for the dying scene it did for the cake-walk, and that the pistol went off five seconds after the man had dropped oftener than at the right time.

I have an idea that John Chinaman saw your correspondent coming when he charged him \$1.50 for a seat. The shows I have seen charge 30 cents at the most, and are glad to take less. If he will tell me where I can get \$2 for a seat in the East, and get an audience, I shall move there at once. I have a good picture show, the best of machines, 15 h.p. of electric light, building well lit inside and out, and electric fans in the hot weather. I don't show old and dirty films; I keep a stock of about 600 subjects which are constantly changed, and I charge 50 cents at the most, oftener 30 cents. I know of four others out here who have all good shows, and, if not Englishmen, are white, and know their business, and I don't know one of them who would put up a shanty and play to beach-combers.

The comparison between the chief London halls and a Chinese-run animated picture show is too ridiculous. No, we are not asleep, though I should never expect your correspondent to admit the fact.—Faithfully yours,

T. J. STEVENSON.

The Bioscope Co., China, February 15, 1907.

[We are very glad to publish our correspondent's letter. The

previous writer, who represented himself to us as the engine of a trading vessel, acted in good faith, so far as we know, in giving his opinions, but we are unable to say why he came to the conclusion reflecting on British cinematography in the East.—"B.J."]

#### THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

To the Editors.

Gentlemen,—I feel sorry for the correspondent in your issue of March 29, 1907, who signs himself "One who would see his profession raised, and not lowered, by the use of the 'M.P.P.A.'." He is evidently so superior to the rest of us that he thinks he is best out of any organisation of any kind.

When one allows false pride and other objectionable characteristics to be imported into matters of this kind no good can be looked for.

I take it that a Professional Photographers' Association intended to include *all* professional photographers, and if that is not the case, another title should be chosen. Why this sneer at "backyard photographers"? Many who would doubtless be described by your very superior correspondent are quite as good as he professionally, but prefer to work in a corrugated iron wooden studio because they do not believe in making a present of a fully equipped brick and mortar building to their landlors in return for being for a few years allowed to rent his premises at good rental.

No doubt your correspondent was able to make most favourable terms, or to purchase suitable premises, but we cannot all do so.

Further, with regard to printing the letters "M.P.P.A." on mounts, I read, *re* this, that: "It is suggested by the committee that on their cards, note headings, invoices, and business stationery, members should print the words 'Members of the Professional Photographers' Association.'" Can you blame members for doing as they are advised to do?

If we are to see our profession raised, do not let us allow our prejudices or any idea of our individual superiority to enter into these matters. Even a "stick-back" producer is a professional photographer, and may be socially equal to your correspondent. Yours, etc.,

A HATER OF CASH.

[There is an important distinction between the use of the designation, "Member of the Professional Photographers' Association" recommended by the Association itself and that of the letters "M.P.P.A." Actually, under the law of this country, any person may use any letters he pleases after his name. He cannot be prevented from doing so, but he can be made a laughing stock, and may be proved to be acting with fraudulent intent by assuming a given title. It is because we desire to add to the strength and dignity of the Professional Photographers' Association that we publicly and privately discountenanced the use of the letters "M.P.P.A." Appended in that shape to a name they may be taken by the public as a proof of efficiency on the part of the photographer, even though the photographer may not have that object in mind when employing them. The risk which a photographer runs in using them is that any interested person can show that the qualification which they imply is the subscription of five shillings annually.—Eds. "B.J."]

THE SERVICE COMPANY, LTD., are organising an exhibition of photographic apparatus, to be held at their premises, 292 and High Holborn, London, W.C. This exhibition, which will include samples of the most recent apparatus of practically all the leading makers, will open on April 15 and continue for a fortnight, during which time demonstrations of the working and use of the various exhibits will be given.

HISTORY OF THE BLEACH-OUT PROCESS.—Dr. W. Neuhaus, in his current number of "Photographische Rundschau," strongly repudiates a recent statement to the effect that the bleach-out process to which he himself has notably contributed, and which is now before the market in the "Uto" Paper of Dr. Smith, of Zürich, was a discovery of Vallot. Dr. Neuhaus points out that the bleach-out paper made in 1899 by the late E. Liesegang, six years before Vallot's, Liesegang's work was qualitatively in advance of that of Vallot, inasmuch as he used certain materials in order to enhance the sensitiveness of the dyes.

## Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### TOGRAPHS REGISTERED:—

Sawyer, Westfield, Dover Road, Walmer, Kent. *Three Photographs of The Rev. Canon D. B. Payne, D.D.*  
 Gilliver, 2, Granville Street, Plymouth. *Photograph of the 'Craces of the 10 Victims of the Submarine "A 8" Disaster in Cansand Bay, 8.6.05.*  
 Ark, 119 High Street, Deal, Kent. *Two Photographs of the Band of the Royal Marines, Deal.*  
 and H. Ancell, 71, High Street, Sandown, I.W. *Photograph of Submarine "B2," stranded on sand in Sandown Bay during fog.*  
 Peterson, 19, Academy Street, Inverness. *Photograph of The Rev. J. J. Black.*

### WING REGISTERED:—

athrie, St. Andrew Avenue, Latch Road, Brechin, N.B. *Drawing of old Arms of the long defunct family of the House of Edzell, Edzell, Forfarshire (1604).*

ENT PHOTOGRAPH.—I have secured the sole right to photograph and publish a very important engineering patent, which will be on the market shortly. Could you tell me my best way of getting the photographs simultaneously published in the greatest numbers of journals and periodicals, so as to get the greatest possible advantage from it.—A. H.

It is difficult for us to advise you as you do not give us a very clear notion of the article. It is not very likely that the newspapers will allow you to indulge in gratuitous advertisement of it.

RIGHT.—Last year I asked a prominent gentleman to favour me with a sitting for his portrait, which he did. I gave him a few copies free of charge. Since then he gave me an order for 1 doz. copies which he paid for. After that I got the photograph registered as I expected a large sale for them "permission being granted me." The point I am not clear about is this: Is the copyright really mine, seeing he paid me for 1 doz.? My reason for asking above is, that a poster firm called upon the gentleman in question for one of the photos, which they have now reproduced and are going about canvassing, and selling copies. If I can prove that the copyright is really mine, can I compel the firm to return to me all copies sold, also how much damages can I claim, as they never asked my permission.

The copyright became yours in the first instance, but you should have obtained a written assignment from the sitter at the time. The fact that subsequent copies were paid for does not affect your rights, but before taking action we should advise you to be prepared with proof that the photograph was to be your copyright in the first instance.

USE.—My wall show case generally has steam on the glass, rendering the photographs hardly discernible to passers-by. Afterwards it streams down like a greenhouse. I have made two 1-in. holes top back, without any improvement. The show case faces N.E., and the back (wood) is warmed by the sun, which probably causes steaming. Can you give me any advice on this matter? I thought I must have a special kind of ventilation without letting in too much damp air in inclement weather, which is not desirable for photographs exhibited for at least three months.—V. LOX.

More ventilation will improve matters; but if the trouble does not disappear it will be best to fit a metal lining in the

case and to attach an extra back to shield the case from heat, the extra back taking the form of a screen an inch or two from the back of the case, thus leaving an air space between the two.

COMBINED BATH.—Being a reader of your JOURNAL, I have written to ask if you will kindly give me a formula for a 16 oz. combined toning and fixing bath to keep before or after using, and to suit any P.O.P.—J. JAMES.

A. Hypo .....	6 ozs.
Ammonium Sulphocyanide .....	48 grs.
Water .....	32 gs.
B. Gold Chloride .....	15 grs.
Lead Acetate .....	150 grs.
Water .....	16 gs.

Take 14 ozs. of A. and 2 ozs. of B.

PLATE ENVELOPES.—We have heard of a system of carrying plates for outdoor work in patent envelopes, only one slide being necessary. By this method a quantity of plates may be carried in a smaller space than slides would take. Could you give us any information respecting the use of these. Are they safe and as simple to use as ordinary dark slides. Where may we purchase them?—DARR SYLVE.

There are several pieces of apparatus of the kind. Messrs. Mackenzie and Co., 17, Douglas Street, Glasgow, were the originators of the system in the commercial form, and you will obtain particulars from them. In our experience the system has proved perfectly safe.

F. VERNON.—We do not know them, and inquiries in the trade have met with the reply that there is no such firm.

F. D.—Try 4, Avenue Road Villas, Goldhawk Road, W. We think the son is in business at this address.

YANG.—We shall reprint the paper, but single parts of the society's journal may be purchased by anyone.

PUZZLED.—If you will commence reading at line 19 of the article you will see it clearly mentioned that the light is to be at a point on the circumference. The points 2 and 2A are intended, we take it, to represent actual positions of the camera; the lines passing through 2 and 2 the directions for the line of the lens and of the gaze of the sitter.

W.—1. We see the articles are in the 1906 list of the firm whose name we gave. The only other likely source is Mr. Tylar, High Street, Aston, Birmingham. 2. There is nothing quicker in printing than the matt varnish. You can fix a mineral paper to the back of the negative with seccotine at the edges, and apply the stump or colour to it, but we prefer the varnish method. Using a pot of dry carmine colour, we have never had a difficulty in applying the colour evenly with the first finger.

CEMENTING CELLULOID TO PAPER.—Can you give me the formula for a perfectly transparent and colourless cement, and the method of using it to unite ungelatinised paper to celluloid, one which will not admit of the celluloid peeling when the paper has dried? I am quite familiar with the method adopted and the appliances necessary in the case of P.O.P., bromide, etc.—J. C.

If the paper is one with a hard surface we should say that it could be made to adhere to the celluloid in the same way as bromide or other prints are, without any cement at all—namely, by soaking the paper in spirit and then rolling the two in contact with a heated roller. If that does not answer you might try a solution of gelatine, say an ounce and a-quarter of gelatine to a pint of water, with a little glacial acetic acid added. The acid, having a slightly solvent on the celluloid, would probably give it a tooth and prevent the paper peeling off.

SCOT.—Yes, you can stop publication of copies as soon as you have registered, but you cannot proceed in respect of infringements before registration.

MOUNTS.—Could you kindly give me an address where I could purchase some mounts same as enclosed corner piece?—A. T. B.

We are unable to identify the mount, but if you send a sample to Messrs. Marion or Fallowfield they will in all probability be able to supply you.

TONING P.O.P.—Will you kindly advise me under the following circumstances:—I have been constantly experimenting, for the last twenty years, in toning prints with gold. As a result, I find that, using ordinary P.O.P. and usual sulphocyanide toning bath, under certain conditions, that any colour or combinations of colours may be obtained. The finished print may be of a

single colour, either black, blue, green, violet crimson, orange, yellow, etc., as well as all kinds of intermediate tertiary hues—or of two or more colours, for instance—the shadows may be bronze-green and the half-tones salmon, or the darkest shades may be peacock green, the middle tones blue, and the light tints crimson, or any other assortment desired. In the case of more than one colour in same print they appear simultaneously in the one operation, and the finished print contains no other metal than gold. What I want to know is, how to proceed to (1) obtain an expert opinion as to whether the process is of any commercial value; if so (2) pecuniary and other help to exploit it?—THOMAS AGER.

We should advise you to approach one or two makers of photographic chemical preparations, from whom you could discover if the process is one they think worth while embodying in a special preparation. If, as we take it, you wish to lay the whole process before an expert, we can give you the name of a gentleman who would give you an expert opinion and who would respect your confidence. We cannot advise you as to exploiting the process.

**A WAGES QUESTION**—If an assistant is away from business for a week through illness, and by the doctor's orders, can he or she claim full or part of salary for that week?—B. L. H.

He or she cannot. The master is not obliged to pay wages in such circumstances unless he has bargained to do so.

**MARINE PHOTOGRAPHY**—Is it possible to take fairly good photographs from a boat while sailing, and which would be the best arrangement for shading sun, etc.?—PHOTOGRAPHER.

Certainly, with any camera with a rapid shutter, say 1/100 of a second. Messrs. Dawbarn and Ward's book, "Photography on Tour" (1s.) will give you some useful hints.

**PEN**—In France, "Photo-Revue," 118, Rue d'Assas, Paris; in Germany, "Deutsche Photographen Zeitung," Karl Schvier, Weimar, and "Photographische Chronik," W. Knapp, Halle a/S. The two latter also circulate in Austria, where there is also "Wiener Freie Photographen Zeitung," Paysegasse 13, Vienna II./16.

**SEASIDE PHOTOGRAPHY**—I should like to obtain a situation with a photographer in a seaside town this summer, as I am advised that I should be better for a year's living near the sea. Can you give me any advice as to how to proceed?—IMPROVER.

We can say no more than that the summer season in seaside resorts begin about June (May in some places), and lasts until September. We should advise you to insert a small advertisement of your qualifications in our columns at the proper time, when you will get into touch with employers requiring help.

**COPYRIGHT**—Last summer I was employed by a camping-out party who were living for several weeks by the river near this town to make a series of photographs of themselves and their camp and boat. I delivered the photographs and retained the negatives, from which in the course of the last few weeks I have issued and sold a good few postcards, the photographs being very attractive subjects and good negatives. I have now heard from one of the party who happened to be in — last week that I must stop the sale of the postcards, or he will take proceedings against me. I told him that the negatives were mine, and I should do as I liked with them, and he now threatens me with an action. What do you advise me to do?

You say "you were employed," and you ought to know that, if you were, you have not the faintest right to make any use whatever of the negatives. You had better make the best terms you can. You are absolutely in the wrong, are guilty of a breach of contract, and if the parties like to go to the trouble they can proceed against you for infringement of copyright. You deserve it.

**MAJOR R. B. (Alexandria)**—We do not supply books or apparatus. We have passed on your application to a firm who will be able to give you a quotation.

**CUTTING HALF-TONE NEGATIVES**—Like most half-tone operators, I have been accustomed to use the iodine-cyanide reducer for sharpening up the dots, and have only one cause to complain of it, and that is the expense. The charges for iodine become quite an addition to the day's expense when a good, big batch

of work is being got out. However, my object in writing you is to ask you if a substitute which is cheaper is known, and so, if you can give me a formula.—RASTER.

You can use potassium ferricyanide instead of iodine. We cannot give you a definite formula, as the quality of the cyanide is so variable, but try adding about  $\frac{1}{2}$  oz. of 10 per cent. solution of ferricyanide to, say, 4 oz. of weak solution of good 30 per cent. cyanide cake.

**C. E. M.**—We should advise you to address your inquiry to Messrs. Houghtons, Ltd., who will probably be able to deal with the matter.

**ALBUMEN SOLUTION**—For the preparation of a certain mixture which I am experimenting with for a certain trade purpose regarding which I may be able to advise you later when I have completed my tests, I require to keep a solution of albumen but find it almost impossible to get this chemical to keep good for any length of time. Can you tell me of anything which will preserve it for, say, three months, something which I can mix with other solutions.—SIGMA.

We should advise you to try pure carbolic acid, using about 1 part of the pure acid to 50 or 60 parts of the albumen. Carbolic acid will mix without harmful effects with a very large number of substances, but we cannot, of course, pronounce definitely in your case, as we are ignorant of the composition of your mixture.

**INQUIRER**—The address of the Professional Photographers' Association is 89, Albany Street, London, N.W. Certainly you can do no better than join the Association.

**RESTORING DAGUERREOTYPES**—I have had sent to me a specimen of a Daguerreotype portrait which is much tarnished and stained. Before taking any steps to its renovation, I should like to ask you if the portrait is liable to be spoiled in the process, and if the method to be followed is difficult?—CHILFORD.

Briefly, the process is as follows:—All dust is first blown off the Daguerreotype, and the latter is then treated with a weak solution of potassium cyanide—say, 10 grains per ounce of water—until the tarnish is removed. It is then washed, first under the tap, and finally in distilled water. It has finally to be dried, the most tricky part of the process. This is done on a small spirit lamp, and requires some considerable skill to avoid drying marks. If you have had no previous experience in the restoration of Daguerreotypes, we should advise you to send the specimen to an expert such as Mr. E. W. Foxlee, 22, Goldsmith Road, Acton, London, W.

**C. S. E.**—Messrs. Staley and Co., 19, Thavies Inn, London, E.C., can send you particulars of the anachromatic lenses.

**PRESS PHOTOGRAPHY**—Can you tell me the best way to get a position on one of the illustrated newspapers as photographer of events and incidents such as are reproduced week by week? I have had a fair experience with focal-plane and reflex cameras.—SUSSEX.

We can only suggest that you apply to the leading illustrated papers, sending specimens of your work, and of any articles you have written. "Willing's Press Guide" (1s.) is as useful a directory of the newspapers as any.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## The British Journal of Photography

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWO PENCE.

## EX CATHEDRA.

### An Exhibition of Survey Photography.

To-day week we shall open at these offices an exhibition of photographs representing that eminently important branch of applied photography in which several societies are now engaged, and in which the National Photographic Record Association, under the presidency of Sir Benjamin Stone, has led the way. The collection of prints which will be on view are, in fact, the most recent acquisitions of the latter body, and have been selected from a number of others by the secretary of the N.P.R.A., Mr. George Scamell, to whom we are indebted for this opportunity of bringing the work of the Association actually before all those who choose to pay a visit to the little gallery in which the photographs will be housed for the next six weeks. We shall refer more particularly to the photographs themselves and to the work of which they are the outward and visible sign as soon as the exhibition is open.

### Harmonising Harsh Negatives.

A substitute for the persulphate reducer is advocated in the current number of "Das Atelier" by Professor Namias in the shape of a modification of the permanganate reducer which the same Italian savant worked out some years ago. Namias employs the permanganate solution as a means of staining the gelatine film. The action consists in the deposition of manganic oxide equally on both high-lights and half-tones of the negative, with the result, of course, that the contrast between the different portions is lessened. The advantages claimed by Namias for the process are its facility for local application by brush, and for its similar local removal by means of a solution of bisulphite of soda of about 5 per cent. strength. The formula recommended is:—Potassium permanganate, 5 parts; water, 1,000 parts; acetic acid, pure, 5 to 10 parts. The negative is soaked in water prior to being immersed in this solution, in which it is allowed to remain until the necessary intensity is reached.

### Blisters on Prints.

It appears that the old trouble of blisters is still being met with by many correspondents, and by others whose complaints we have received. Very differing opinions are expressed as to the cause, and we should like to point out that it is difficult to even guess at the cause when the particular kind of blister is not described. Most correspondents seem to assume that the blister is between the gelatine film and the paper support, but if they take the trouble to dissect the various examples of the defect that they meet with they will find that there are two varieties. One is between the film and the paper, and the other in the body of the paper. If a cut is made right through the blister it will often be found that the underside of the gelatine is coated with

paper, torn or split away from the body of the support. Blisters of this kind generally disappear on mounting, and can generally be cured by soaking the paper in a very fluid mountant; but blisters consisting of gelatine only are practically incurable. The paper blisters are certainly suggestive of imperfect or impure paper, but as a matter of fact we have traced them, in the case of one brand of P.O.P., to the injudicious use of a salt bath. If the bath was not used, no blisters appeared, while they broke out with the greatest readiness when the salt was again employed. The paper may have been defective, but if so, its defects only became manifest by faulty manipulation; and, in spite of the opinion of our correspondent, "J.P.," on page 261 of a previous issue, we are much inclined to think that faulty manipulation is the prime factor in all such mishaps. Paper blisters are probably due to violent local chemical reactions that should be avoided, and gelatine blisters partly to similar causes and partly to mishandling. A slight dragging touch from the corner of another print may cause a blister sometimes, and the over-use of hardening agents may encourage the separation of the gelatine from its support. Considering the delicate nature of a photographic image, the manner in which it is handled, and the sometimes excessive variety of more or less unknown chemical reactions to which it is submitted, we are not so much surprised at the occasional appearance of blisters as at their comparative infrequency. We will return to the subject again shortly, when we will prescribe a course of procedure which has proved effective in preventing blisters.

#### Silver Chloride Crystals.

Every reader will probably be familiar with the classic figures given by Eder of crystals of silver bromide, and others will remember that quite recently (in our issue for February 15, 1907) Dr. W. Scheffer's photo-micrographs of crystallised silver bromide were published. According to R. E. Liesegang it is extremely easy to obtain crystals of silver chloride by coating a sheet of glass thinly with a 0.2 per cent. solution of gelatine containing the same amount of salt. On drying the salt crystallises out in treelike forms, and if the film is then painted over with a 1:1 aqueous solution of silver nitrate, the silver chloride formed takes the same shape. If treated with a developer, the metallic silver is also reduced in the same shape. Liesegang points out that the trick in forming this and similar pseudomorphs is in the use of the very strong solution of silver nitrate. There is thus formed at the commencement of the reaction a skin of silver chloride, which is penetrated by the silver nitrate with great difficulty. If a dilute solution of silver is used the chloride is in excess, and the crystalline form is destroyed. As, according to Pringsheim, these skins are always very opaque or difficult of penetration for salts of equimolecular weight which act upon one another, Liesegang proposes the name for them of Pringsheim's skins or films.

#### Cutting in the Antipodes.

A Sydney correspondent sends us copies of the newspaper advertisements of two photographers in that city, which show the lamentable condition of competitive cutting which is being resorted to. We are called upon to witness the spectacle of two leading studios bidding against each other for trade which cannot surely be profitable to either. The special offer by each is a framed "Rococo" enlargement for 7s. 6d., the work, so we learn from our correspondent, being 25 x 21 in., and distinctly good in quality. It may be cold comfort to our Australian friends to be told that almost every populated district in England could show competition in photographic portraiture even keener than the instance which has been cited above. For all of which

those who share our own regrets at this feature of modern commercial photography are able to prescribe no remedy save that which has been adopted by some men, whose position has been assailed by the very cheapest workers putting up simultaneously both the quality and the quantity of their own productions. As the continuance of such prices must react unfavourably upon assistants in Australia, we would suggest to the association of employers in that country that the position of influence which they believe them to occupy might be utilised in no better manner than in discouraging the persistence of these cutting practices.

### THE POISONS ACT.

FROM the Drug Stores Association of Great Britain we have received a communication, which appears in our "Correspondence" columns, calling attention to the Government Poisons Bill, which is to be referred to a Select Committee, and suggesting that photographic dealers should make an attempt to obtain some concessions in the sale of poisonous chemicals used in photography. At the present time only two chemicals appearing in Part I. of the schedule of the Poisons Act which are employed in photography are cyanide of potassium and bichloride of mercury—corrosive sublimate as it is called in the Act. Unless a photographic dealer is a pharmaceutical chemist, he renders himself liable to a penalty of £5 if he sells either of these. If he sells a solution of the latter and one of cyanide of silver, to be used for the intensification of negatives (Monckhoven method) he is equally as responsible as if he sold the two salts in solid form. Now cyanide of potassium is, of course, but little used for photographic purposes compared with what it was in the wet collodion process, though the mercury salt is still largely employed; but it is a question whether dealers will trouble themselves to deal about these two substances alone. But the Pharmaceutical Society have for a long time been anxious to get the Poisons Act, necessary to the industrial arts, added to the Schedule so as to restrict the sale of them to pharmaceutical chemists, and thus, allegedly for the protection of the public, to give them a monopoly. Most of the developments now used are poisons, and we have heard of one dealer, at least, from our old friend "pyro," through a solution being swallowed by accident. If the whole of new developing agents were scheduled, dealers could no longer sell them, users would perforce have to go to the pharmaceutical chemist, and would probably have to pay more for them. This is a matter that dealers may do well to give attention to just now. One of the suggestions of the Association is that any person should be allowed to sell any poisonous chemicals used in photography without incurring a penalty, provided they are sold in a wrapper, box, or other vessel bearing the name of the pharmaceutical chemist as the compounder or manufacturer of such poison, together with the name and address of the seller. Why, we should like to know, should it be necessary that the chemicals be compounded by a pharmaceutical chemist for the dealer to be allowed to sell them? The latter best knows the requirements of photography. It may frequently be the case, he wishes to sell to his customers a preparation containing a poison scheduled under the Act, the package, according to this recommendation, must bear the name of a pharmaceutical chemist, by whom only it must be prepared. This suggestion looks very like keeping a monopoly in the hands of pharmaceutical chemists.

There is one suggestion in the circular with which we, and we think most of our readers, are in perfect accord, which is that the administration of the Poisons Act should be taken out of the hands of the Pharmaceutical

Society and placed in those of the local authorities, when everyone would get impartial justice, and prosecutions for mere trivial offences without receiving any warning would be at an end." At present, if a photographic paper sells a little bichloride of mercury, or an oilman a "paper" containing arsenic, the Pharmaceutical Society prosecutes and recovers a £5 penalty, which goes into its pockets. Yet the pharmaceutical chemists are the worst infringers of the Poisons Act, as they frequently do not conform to the terms under which they are allowed to sell poisons. For example, only quite recently a chemist sold to a person just liberated, on trial, from a lunatic asylum, some bichloride of mercury, with which she committed suicide. At the inquest the chemist admitted that he had not complied with the Act, and was severely censured by the coroner. Although we have read of many prosecutions by the Pharmaceutical Society of photographic dealers, oilmen, and others for infringements of the Act, we do not remember having heard of a single one against a member of its own body for its infringement. The administration of the Act were placed, as the Drug Association suggests, in the hands of local authorities, there would, probably, be more impartial justice administered all round.

#### KEEPING SENSITIVE CARBON TISSUE.

Every year sees an increasing popularity in the carbon process, alike with professionals, and amateurs, and what is still more important, the public generally. The tising and drying of carbon tissue is looked upon upon as being a troublesome operation, though as a matter of fact it is a very simple one. The tissue can now be obtained from any of the makers in the sensitive state, and it will keep in working condition for about a fortnight or much longer, that is, if kept under the usual conditions. This short-keeping quality often entails some waste, and the whole of the purchase may not be used up before it becomes so insoluble as to be unworkable, insolubility is really brought about by moisture in the gelatinous tissue. It may not be known to every one that if the tissue is absolutely dry it may be kept several months after sensitising in a perfectly workable state, say, if it be stored under the same conditions under which platinum paper can be kept. A few years ago the Autotype Company introduced a preservative case for sensitive carbon tissue. It was a flat case with a small receptacle at one end for

chloride of calcium. The tissue is kept flat under slight pressure so that it does not curl. At the time of its introduction the company furnished us with one of these cases filled with sensitive tissue, which we kept for three months before we printed it. We found, after this long keeping, that the tissue worked as well, and yielded prints in every way as good, as if it had been used at the time it was made. This preservative action is due to the chloride of calcium absorbing the moisture from the gelatinous film and keeping it perfectly dry. The same result would, of course, be secured had the tissue been stored in an ordinary platinum-type tin, although it is necessary in the case of carbon tissue for the pieces to be kept as flat as possible.

It is well-known to everyone, we believe, nowadays, that in the carbon process the prints become darker by being kept long after they are printed, therefore it is recommended in all the manuals, and by most writers on the subject, that the pictures be developed as soon after they are taken from the frame as possible, unless allowance be made for this action in the printing. Yet it is not always convenient to develop the pictures directly they are printed, and the longer they are kept the more over-printed they will turn out when developed; and it is not easy to estimate the under-printing necessary for a given time of keeping. Hence it may be well to point out that this continuing action is entirely due to the presence of moisture in the tissue, and if there is no moisture there is no continuing action, even if the prints are kept for many months. Therefore, if the prints, after they are removed from the printing-frame, be put directly into a calcium case they may be kept until any convenient occasion for development. In this way they have been kept for six months, and have proved at the end of that time no darker than if they had been developed immediately after printing. If the prints have to be kept for a long time—a month or two—before development, it will be well to dry them somewhat before the fire, previous to putting them into the case, to get rid quickly of some of the moisture, but they should not be made actually warm, as heat accelerates the continuing action. If the tissue, either before or after exposure, is stored in a cylindrical case, the coated side should be rolled outwards, as if rolled the other way there would be a danger of its cracking when unrolled. It is for this reason that flat cases are preferable to cylindrical ones. The object of these notes is to point out that sensitised carbon tissue, if kept under the conditions just mentioned, will remain in good working order as long as will the average P.O.P.

## SOLARISATION AND THE THEORY OF A COMPOUND LATENT IMAGE.

(A paper in "Photographische Korrespondenz.")

Under the title of "Experiments on the Development of the Latent Image,"<sup>1</sup> I published recently a treatise in which I showed that the image developed with indoxyl or thioindoxyl is not of an homogeneous nature, but consists of an indigo and a silver image. On the ground of the theoretical considerations and supported by further experiments, I came further to the conclusion that the substance of the latent image could not be of an homogeneous nature, but consisted very probably of a mixture of silver per-bromide  $\text{Ag Br}_2$  and sub-bromide  $\text{Ag Br}$ , in which in place of the latter the expression  $\text{Ag} + \text{Br}$  should be placed.

Further mentioned that development with indoxyl can illustrate the phenomena of solarisation. This latter

phenomenon I have more closely examined, with the following results.

In order to prepare a solarised image, gelatino-bromide plates, of about 12 deg. Scheiner,<sup>2</sup> were exposed behind a Chapman-Jones scale photometer to diffused daylight, between 10-12 mid-day on a cloudy November day, for ten minutes at two metres distance from a window.

When a plate thus exposed was developed with the above mentioned indoxyl solution,<sup>3</sup> a beautifully solarised image was obtained: numbers 1 to 10 were strongly solarised, 11, 12, and 13 were a "neutral zone," whilst the remaining numbers to 25

<sup>2</sup> This is about equal to 100 H and D.—Eds. "B.J."

<sup>3</sup> For the sake of brevity, development with indoxyl to an indigo image will alone be mentioned; the behaviour is exactly the same with thioindoxyl.

showed a normal negative. The fixed plates when examined by daylight showed the normal green colour, which has already been mentioned. When the plate was placed in a cyanide solution, to which some potassium fericyanide had been added, the "silver image" dissolved quickly, whilst the pure blue indigo image was left behind. This indigo image was not solarised, but showed the gradation of a normal negative, from which one must conclude without further argument that the silver per-bromide constituent  $\text{Ag Br}_2$  of the latent image was not solarised.

Lüppo-Cramer has proved<sup>4</sup> that reversal of the image is not obtained by physical development of a solarised and primarily fixed plate. I proved the correctness of this statement by developing one of these solarised plates after primary fixation with the sulphocyanide-metol-silver physical developer given by Haschek.<sup>5</sup> A clear negative with normal gradation was the result.

We therefore come to the remarkable fact: in a silver bromide film exposed sufficiently long to cause solarisation neither the silver per-bromide constituent  $\text{Ag Br}_2$  nor the silver sub-bromide  $\text{Ag} + \text{Ag Br}$  is solarised; the two developed chemically together give, however, a solarised negative. This apparently paradoxical phenomenon finds a natural explanation in the following considerations:

Assuming that my views on the nature of the latent image are correct, the film in an exposed dry plate is composed of the following three substances:

1. Silver per-bromide  $\text{Ag Br}_2$ .
2. Silver sub-bromide  $\text{Ag}_2 \text{Br}$ , or  $\text{Ag} + \text{Ag Br}$ , and
3. Unchanged silver bromide in the ripened highly sensitive form.

With continued exposure the quantity of per-bromide and sub-bromide increases in molecular proportion. A reversible action—that is, a reversal of the image—as proved above, does not take place either with the latent per-bromide or latent sub-bromide. Naturally the proportion of silver bromide must decrease in the same ratio, as with continued exposure the per-bromide and sub-bromide increase.

<sup>4</sup> "Phot. Korr.," 1905, p. 260.

<sup>5</sup> "Eder's Jahrbuch," 1899, p. 476. Haschek's formula is:—I. Ammonium sulphocyanide, 24 gms.; silver nitrate, 4 gms.; sodium sulphite, 24 gms.; hypo, 5 gms.; potassium bromide, 0.5 gms.; water, 100 gms. II. Metol, 15 gms.; sodium sulphite, 150 gms.; water, 1,000 ccs. For use mix about 6 parts of No. I., 54 parts of water and 34.40 parts of No. II.—EDS. B.J.

In the decrease of the silver bromide I see the cause of solarisation.

For, if we describe chemical development as a disassociation by the developer of  $\text{Ag Br}$  into  $\text{Ag} + \text{Br}$  through the agency of the "silver germ" of the silver sub-bromide, it is obvious that by continued exposure with simultaneous increase of sub-bromide, "silver germ," and decrease of silver bromide, there must appear at a certain stage a condition of equilibrium—that when to a molecule of sub-bromide or to every atom of "silver germ" there is still one molecule of silver bromide. If the plate is developed at this stage it will perhaps give the maximum density. If the exposure is pushed further, beyond the state of equilibrium, the sub-bromide increases and the bromide decreases. If the plate is now developed, the "silver germ" of the sub-bromide finds less reducible silver bromide than in the previous stage, and the natural result of this is that the density of the negative must decrease.

Against these arguments one may advance the statement which I made in my previous papers, that in development with indoxyl the silver per-bromide is reduced to bromide, therefore there cannot be a decrease of the latter. This objection would doubtless be justified if the two images, the silver and the indigo image, were simultaneously formed; this, however, is not the case, for the silver image is formed first, and only with continued development is the indigo image gradually formed. This can be easily proved by developing an exposed plate for only a short time in the indoxyl bath—that is to say, only till the details of the image are distinctly visible. If the development is then interrupted and the plate fixed, a pure silver image is obtained, black-brown when looked through, with strong metallic lustre. The fact must also not be overlooked that the silver bromide formed by the reduction of the per-bromide is simply chemically-produced bromide, and in its photo-chemical properties in all respects totally different from the "ripened" bromide originally present, and obviously only reduced with difficulty, or not reducible by the "silver germ."

The above conception of solarisation most satisfactorily explains the fact that solarisation can be remedied by careful treatment with bromine water. A part of the existing silver sub-bromide,  $\text{Ag} + \text{Ag Br}$ , is converted back into  $\text{Ag Br}$  by the bromine, so that the amount of sub-bromide in the film is lessened, that of the bromide, on the other hand, increased, so that the normal un-solarised condition of the plate is more or less approached.

B. HOMOLKA

## HALF-TONE NEGATIVES: AND A SUGGESTION FOR SECURING UNIFORMITY IN THE SAME.

(A paper read before the Royal Photographic Society.)

THE remarks I have to make are founded on something I published some years ago when it passed without comment, either favourable or otherwise. At that time half-tone work interested comparatively few, and those few were following it for a living, jealously guarding their secrets, and keeping their own counsel. Now the production of half-tones is no longer shrouded in mystery, and I hope to-night for a discussion and consideration of the suggestion.

For some years I have not carefully followed the photographic press, but before writing this paper I made efforts to ascertain that in the meantime nothing had been published that would prevent it being of interest. I found with regret the most notable development in half-tone work of late has been the steady cutting of prices.

Everything in block production depends on the perfection of the negative, and I am afraid this cutting of prices must often mean the using of a negative that the operator recognises full

well is not up to standard, but with the low price ever before him, he fears that to take another negative would mean a loss of that particular block. The negative for really successful work must come within very much narrower limits of perfection than a negative for any other purpose. One firm I know produced the best work, years ago had a man sitting in judgment on every negative produced, destroying all such as were short of perfection, and that course I thoroughly endorse; it means the loss of many negatives, but all after processes are much simplified and an ultimate saving effected, I believe—certainly a high standard of work is maintained. It is the complexity of manipulation that leads to uncertainty in the production of high-class work, and too often tempts the operator to remark, "That will do," they must "dodge the printing a bit," or "The fine etching will put it right." I may here remark that a large percentage of the fine etching is a clumsy and expensive expedient for making use of a faulty negative, and possibly the production of rea-

uniform negatives for half-tone is the most difficult of all photographic problems; at any rate, I expect those who do the work think so. The full meaning of regularity is this—the negatives must take a uniform time to print and a uniform time to etch; the printer and etcher should be merely mechanics, performing operations governed by the same set of conditions—exposure, and time, and fine etching should be practically eliminated.

As to the failures, many operators, I am afraid, attempt too much and court too much complexity in their methods. The high percentage of good work under present conditions is very wonderful, but if by simpler means more can be done, why should we not adopt the simpler conditions and work, if possible, by rule, instead of by "judgment"? As to the conditions that govern half-tone work, I am unaware of any scientific investigations that we can regard as adequate. Theoretically, the work cannot be done at all; in practice we know it can, but as to exactly what part the various factors such as screen distance, stop, shape of stop, pin-hole effect, what I term general lens effect, the vignetting action of the screen, the spread in development, cutting, and intensification, have in making up the total will perhaps never be determined—there is no money in such investigations—and the matter is one of extreme complexity. In the "British Journal" twelve years ago I published and pretty fully illustrated some experiments with regard to stops of various shapes, and the following year Dr. Eder reported some experiments in the same direction by Placezsk, but many of the conclusions arrived at were unacceptable to me, a single variation in their details giving contradictory results. A few details may be of assistance to those unfamiliar with the practical applications of the half-tone process (if there be any here), in following my remarks.

First the screen is separated from the sensitive plate by a distance usually varying, the screen being adjustable. Some operators vary this adjustment with every exposure, a method which sometimes causes unevenness; for when the movement is worn there is difficulty in maintaining parallelism between screen and plate, and that results in a difference in the effective size of the dots in varying portions of the plate, a difference in the joining up and an irregularity of the dots from end to end of the plate.

I advocate working with the screen at a permanent distance eliminating the possible want of parallelism, and fixing one factor, the screen distance; the separation may vary considerably in quite successful work, providing that the stop and exposure are in harmony with the distance—if relatively too close the screen will be too apparent in the result and much of the contrast of the copy cut out. If screen and plate are too far apart relatively there is difficulty in getting properly defined dots, and in the high lights the dots run together too fully, producing too much contrast. This may be corrected in three ways at least:—

- Altering screen distance.
- Altering stop, its size, or shape.
- Altering time of exposure.

Some operators use one method of correction, some another, and very many alter all three conditions in varying degree and as their "judgment" may dictate.

The operator who gets the correction in the simplest way by altering the least number of factors, is the cleverest operator, though there are some who seem inclined to think that the man who makes one alteration only cannot possibly be so clever as he who makes three.

**Stops.**—Here again complexity seems the rule—many operators use two stops during an exposure, some three—claiming to get better gradation, and I have heard of four being used and recommended as giving better gradation still—possibly more correct gradation is obtained by the use of many stops (if a change is to be made at all), but I have convinced myself by practical experiment as well as theory that between two stops there is a mean or average stop that will give a better result and more

easily than the use of two if our object is the true reproduction of the gradation of the copy—an important point is, you get clearly defined dots instead of two or three superimposed dots with ill-defined edges, the dots being, in fact, surrounded with a vignetted fringe. As to gradation with two stops there is a jump from one to another, and unless a certain exact balance is struck between the two exposures whatever the jump is, from one exposure to another it is present in the dot translation. Three and four stops will give better gradation because the jumps from one to another are less violent, i.e., the error is less apparent because divided into smaller portions; it is still there, however. But I again repeat, there is an average stop that will give a better result at one operation, and one operation being better than three or four, I advocate relying on the simpler method.

With all these factors each operator becomes a law unto himself; he may strike an exact balance occasionally, but I have never met one who could convey any law or regulation for what he did to another.

An important question is—are multiple stop exposures a necessity or a custom? I believe the latter. I know that by ringing the changes with large and small stops faulty copies can be modified and improved, and this improvement is often put as the reason for such action; but, after all, there is still a mean stop between those that will produce the same modification; it is merely a matter of correct selection, and my advice is—try to select one, not two. The reduction of the number of stops makes for simplicity, and therefore let us use one stop of the correct size, rather than two, or more, that are individually incorrect.

I do not propose giving exact conditions for each worker; the offered rules must be applied according to circumstances. I worked under conditions that some regard as fatal to success. The light, the focal length of lens, the plates, and especially the screens, their coarseness or fineness, the stop and its shape, and, in fact, every tool and part, may be different to what I used, but no one need make changes in these directions. I will illustrate the principle in such a manner that anyone can apply the conditions of exposure according to the circumstance under which they have to work.

The first need is a correct exposure, and a standard artificial light, known sensitiveness of plate and a similarity in the work help materially. Success will depend on the admission to the camera of the precise amount of light required by the other conditions of exposure, for the latitude is very narrow. A good standard copy should be taken and experimented with until the conditions produce an ideal result, then analyse very carefully such conditions. They may be as follows, and I here quote from my own experience:—

Fixed screen distance .....	$\frac{1}{8}$ inch.
